THE THEORY OF DESCENT

Studies in the Theory of Descent. By Dr. Aug. Weismann, Professor in the University of Freiburg. Translated and Edited by Raphael Meldola, F.C.S. Part II. On the Origin of the Markings of Caterpillars. On Phyletic Parallelism in Metamorphic Species. With Six Coloured Plates. (London: Sampson Low, Marston, Searle, and Rivington, 1881.)

THE first part of this work, devoted to an examination of the phenomena of seasonal dimorphism in butterflies, was noticed a little more than a year ago (NATURE, vol. xxii. p. 141). We now have a second instalment of much greater bulk, comprising two separate essays. In the first and most important of these Dr. Weismann gives us the results of a detailed study of the changes in the markings of the caterpillars of the Sphingidæ during the course of their growth and development, and enters at great length into the various questions to which the phenomena observed give rise. Accepting the doctrine that the *ontogeny* or development of the individual gives us a more or less accurate notion of the *phylogeny* or course of development of the race, he endeavours with some success to determine the ancestral forms of the various genera of the Sphingidæ by means of the successive changes of form and coloration of the larvæ. The main facts which he has here established are, that all the larvæ are born of a uniform tint—that the first markings are longitudinal lines—that the oblique lines when they exist always appear later, and the ringed or ocellated spots last of all. Great changes of colour also occur in some species, but all the more important changes, whether of colour or marking, only take place after the larvæ have acquired a considerable size. From the whole assemblage of facts in this branch of the inquiry he deduces the following three laws of development:—

"1. The development commences with a state of simplicity, and advances gradually to one of complexity.

"2. New characters first make their appearance in the last stage of the ontogeny.

"3. Such characters then become gradually carried back to the earlier ontogenetic stages, thus displacing the older characters until the latter disappear completely."

These laws are liable to be modified in various ways by the influence of natural selection, and especially by the need for protection, whence arise the various markings of the different groups, and the peculiar divergences often noted in their development at corresponding ages.

Having thus established the general developmental history of the markings of caterpillars, and explained by a few simple principles the chief anomalies they present, Dr. Weismann passes on to the still more interesting inquiry as to the biological value or actual meaning and use of the markings in each individual case. He first shows that colour itself, irrespective of marking, has a distinct biological value, being always either protective or a signal of uneatableness. The Sphinx larvæ when young are almost always green, resembling the leaves of the plants on which they feed and rest. When they get larger, however, they frequently change to brown, and this change is always accompanied by a change in habits, the insect feeding at night, but during the day concealing itself on the ground or amidst dead leaves and branches. This occurs chiefly among the species which feed on low shrubs or herbs and can thus easily descend to the ground to conceal themselves during the day; while those which feed on large trees acquire markings which assimilate them more completely to the foliage or flowers which surround them. The simplest form of marking—longitudinal stripes—is common on all caterpillars which feed on grasses or other plants in which straight *lines* are a prevalent feature, and this style of marking is that which usually appears in the young sphinx larvæ. But as they grow larger diagonal stripes or bands variously tinted or shaded appear, and this style of marking is found to assimilate so well with the oblique veining of the leaves that the caterpillars are very difficult to see when resting among them. This is the case even when the oblique lines are margined with violet or other bright colours, since, however conspicuous these markings may be when the insect is examined in captivity, they are found to blend perfectly with the lights and shadows of the foliage which surround it in its natural habitat. As an example we have the following account of the brilliantly coloured larva of the Death's-Head Moth on one of its natural food-plants:—

"At Cadiz on the hot, sandy shore, *Solanum violaceum* grows to the height of three feet, and on a single plant I often found more than a dozen *Atropos* larvæ resting with the head retracted. It can easily be understood why the lateral stripes are blue when one has seen the South European *Solaneæ*, on which this larva is at home. *Solanum violaceum* is scarcely green: violet tints alternate with brown, green, and yellow over the whole plant, and between these appear the yellow-anthered flowers, and golden yellow berries the size of a greengage. Thus it happens that the numerous thorns, an inch long, between which the caterpillar rests on the stem, pass from violet into shades of blue, red, green, and yellow."

Many of the adult sphinx larvæ however are adorned with ring-spots or eye-spots, and these have been found to serve two distinct purposes. Sometimes they occur on several of the segments, but of slightly different sizes, as in a North American species (*Chærocampa tersa*), the red spots on which imitate the small red flowers of the plant on which it feeds; while in the European *Deilephila hippophaes*, the grey-green larva with orange-red spots so exactly assimilates to the foliage and fruit of the sea-buckthorn on which it feeds, that Dr. Weismann has often shown to people as many as six or eight of the large caterpillars on one buckthorn branch without their being able at once to detect them. In other cases we find very large eye-spots on the fourth or fifth segments only, coupled with the habit of retracting the head and first three segments, so that an appearance is produced of a broad head with two very conspicuous eyes. Whenever the insect is disturbed it thus retracts itself, and it has often been conjectured that the effect is to frighten away its enemies. This Dr. Weismann has proved to be actually the case. On placing the larva of the Elephant Hawk-Moth (*Chærocampa Elpenor*) in a trough used for feeding fowls, a number of sparrows and chaffinches flew down from the neighbouring trees to pick up some stray food.

"One bird soon flew on to the edge of the trough, and

Digitized by Google

was just about to hop into it when it caught sight of the caterpillar, and stood jerking its head from side to side, but did not venture to enter. Another bird soon came, and behaved in a precisely similar manner; then a third, and a fourth; others settled on the perch over the trough, and a flock of ten or twelve were finally perched around. They all stretched their heads and looked into the trough, but none flew into it."

On removing the caterpillar the birds again assembled, and at once entered the trough to feed. Fowls were also frightened at first, and would draw back just as they were going to peck at the caterpillar. At last, after several had tried, and even made ineffectual attempts to peck, one more courageous than the rest would actually touch it, and after a time, finding nothing disagreeable, the insect would be swallowed. In the genus Deilephila, however, there are uneatable caterpillars, and these have strongly contrasted black and white or yellow spots combined with the habit of fully exposing themselves upon their food plants. Dr. Weismann experimented with two species (*D. galii* and *D. euphorbiæ*) and found that they were refused by birds, though the latter was eaten by lizards. It is to be noted however that the experiments were made with a South European species of lizard, not that of Germany, so that the result has not a direct bearing on the point.

The general conclusion at which Dr. Weismann arrives is, that all the varieties of colour and marking occurring in the Sphingidæ have a distinct biological value, and can in every case be traced to the action of natural selection and correlation of growth.

The next essay is not quite so interesting or important. It is an endeavour to prove, by a distinct line of inquiry, that the markings of the larvæ are not due to a "phyletic vital force" or to general laws of growth and development. The different groups of Sphingidæ are minutely examined and compared in their three stages of larva, pupa, and imago, and it is shown that the changes that occur from species to species in each stage are to a great extent independent of the changes in the other stages. Numerous examples of this want of phyletic parallelism are given, and it is hence argued that the modifications which occur must be due to an adaptation to the special conditions to which the insect is exposed in one or other of its states, not to any innate law of variation and development, which, it is argued, would affect all the stages *pari passu* and produce a "phyletic parallelism" which does not actually exist. The same general facts are shown to prevail, not only among Lepidoptera generally, but among all insects and crustacea—or generally among all organisms which undergo a metamorphosis.

This instalment of the work has been admirably translated and edited by Mr. Meldola, who, in a series of valuable notes and an Appendix, has brought up the information on every branch of the inquiry to the latest date. The six coloured plates of larvæ in their several stages are very well executed, and serve to illustrate the somewhat complex discussion in a clear and effective manner.

ALFRED R. WALLACE

OUR BOOK SHELF

The Wandering Jew. By Moncure Daniel Conway. (London: Chatto and Windus, 1881.)

THIS last volume of Mr. Conway's is a study, not only of the legend of the Wandering Jew, but with it of the large group of analogous myths of undying men who from a[g]e to age wander over the earth, or sleep in caverns, or a[re] translated from among men into divine regions, when[ce] however they come back and show themselves still l[ive] men. The interest of these stories in the history [of] philosophy lies in their keeping up men's early ideas [of] life and death. One of Mr. Conway's purposes in [dis]cussing them is to draw attention to their being relics [of] the primitive period when men were still so far fr[om] definitely realising the nature of death, that they had [no] difficulty in regarding kings, heroes, and prophets [as] having only departed for a while from among them, [to] return in a future age to rule and protect their expe[ct]nations. In comparative mythology this group of st[or]has some importance. They show the beliefs of va[rious] races running curiously into one another, as where t[he] Lancashire peasant still hears in the cry of the plover [the] wail of the Wandering Jew, or in the Harz Mountains his myth has got mixed with that of a grander wander[er] the Wild Huntsman, who courses with his storm-cl[oud] across the sky. The storm-demon whom mythic [fa]imagines rushing through the air is often called a *Ma[n]cabee*, and Mr. Conway points out why he has this na[me]. It is because of a verse in the Second Book of Ma[c]bees, chap. v., which, by the way, is a good instance of [the] personal forms taken by the fancy of an excited peo[ple]. "And then it happened, that through all the city, for [a] space almost of forty days, there were seen horsemen running in the air, in cloth of gold, and armed with lan[ces] like a band of soldiers." Unfortunately some other et[y]mologies made or quoted by Mr. Conway are not [as] reasonable as this. When the names of biblical perso[n]ages, *Herod* and *Ahasuerus*, find their way into *European* myths, it may not be easy to explain how they *got there*, but at any rate it is better to leave them *alone than to* make up imaginary and even impossible German or Scandinavian forms, *Haar-Rote*, *As-Vidar*, to account for their presence. It would be easy to take exception to many of the arguments in this volume, but at any rate there are many interesting points in it.

A Short Sketch of the Geology of Yorkshire. By Charles Bird, B.A. (Univ. Lond.) (London: Simpkin, Marshall and Co.; Bradford: Thomas Brear, 1881; pp. and Map.)

Geological Map of Yorkshire. By the same Author. (Edinburgh and London: W. and A. K. Johnston; Bradford: T. Brear, 1881.)

IN the preface of this book, written by way of dedicat[ion] it is represented to be a "small and cheap volume suited to the 'general reader' and tourist." It is impossible say that it is not a useful and interesting one. Some good work has been done on the county, though scatter[ed] through very various publications, that a short r[é]sumé cannot fail to be of value; but there are books and bo[oks] and if we measure this by what it might have been, [it] poor indeed. It resembles, in fact, geologically speak[ing] a kind of boulder clay, full of fragments of solid [rock] brought from a distance—we will not say to be deposited in mud—but certainly scratched and rubbed in the pro[-]cess. In the beginning of the volume is a list of the surrounding mountains whence the boulders have been derived, but it is not a complete one; and the source of each fragment is not indicated in the body of the text. Its great defect is that it is unstratified; in other words the extracts are not duly digested, but thrown together [as] out sorting, and with very little alteration; so little indeed that it would not be difficult to trace them to their sources. Thus under the head of "The Carboniferous Period" we have a brief explanation, from a popular lecture, "how from the general mineral character of a rock the circumstances under which it was formed can often be predicated." Then under the head of "Salt water deposits" we have twelve pages on the origin and contents of the Victoria

Digitized by Google

Cave, which ought surely to belong to the chapter on the "Recent Geological History of Yorkshire," only that the latter happened to be written by one who confined himself to the Holderness drift. Under the head of "The Permian Rocks" there is an exposition of the views of those who would reintroduce the old (not recently suggested) name Poikilitic to include the Trias. It was a pity the author was not acquainted with any recent papers on the series above the Lias, for there are no good boulders in this part of the book. Mr. Hudleston's admirable papers on the Yorkshire Oolites seem to have been written in vain, and there have been modern papers also on the Yorkshire Chalk. It was perhaps excusable for our author to conclude that the third edition of Prof. Phillips' "Yorkshire Coast" contained all the most recent information, though every East-Yorkshire geologist knew that it did not. In examining a work on local geology it is always well to see where the author lived, for the surrounding country will be the best described. So it is here; the best part of the book is the description of the Middle and Upper Coal-measures, which are well developed in the neighbourhood of Bradford. For East Yorkshire and the coast the book is of little value.

The topography of the map requires no other guarantee than the name of the constructors for its excellency. The south-western part of the geological colouring derived from the Geological Survey maps is also very good. Nor can we complain when lack of published material prevents accuracy elsewhere, though it is a reason for regretting the slow publication of the Geological Survey maps which have been long ago completed; but when the whole of the Vale of Pickering is coloured Neocomian, and a patch of the same is placed in the south near Cave, scarcely an acre of rocks of that age being discoverable in the former, and none in the latter locality, one is led still more to regret that the author's map should be spoiled by his not knowing Mr. Hudleston's papers and relying on Prof. Phillips. But he has surely introduced a little mistake of his own, which will be very serious to visitors to the popular watering-places of Scarborough and Filey. The Castle Rock and Filey Brig are coloured —one Lower Oolite and the other Neocomian, whereas they are both what the author would call "Middle Oolite"! It will take more than Mr. Bird to write a good "Geology of Yorkshire."

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Leaves Injured at Night by Free Radiation

FRITZ MÜLLER, in a letter to me from Sta. Catharina in Brazil, dated August 9, supports the view which I have advanced with respect to leaves placing themselves in a vertical position at night, during their so-called sleep, in order to escape being chilled and injured by radiation into the open sky. He says: "We have had last week some rather cold nights (2° to 3° C. at sunrise), and these have given me a new confirmation of your view on the meaning of the nyctitropic movements of plants. Near my house there are some Pandanus trees, about a dozen years old; the youngest terminal leaves stand upright, whereas the older ones are bent down so as to expose their upper surfaces to the sky. These young leaves, though of course the most tender, are still as fresh and green as before; on the contrary, the older ones have suffered from the cold, and have become quite yellowish. Again, the leaves of *Oxalis sepium* were observed by me to sleep in a very imperfect manner during the summer, even after the most sunny days; but now, in winter, every leaflet hangs down in a perpendicular position during the whole night." It is a new fact to me that leaves should sleep in a more or less perfect manner at different seasons of the year.

CHARLES DARWIN

Red Rainbows

THE account in NATURE, vol. xxiv. p. 431, of a pink rainbow seen from Mr. Tennyson's house, recalls to me a rainbow which I witnessed in July 1877 over the Lake of Lucerne from the promenade in front of the Schweitzerhof. The bow in question appeared at sunset, when the whole sky, east and west, was lit up with ruddy tints; and just before it faded out, the bow itself, which was a very brilliant one, showed only red and orange colours in place of its usual array of hues. No fewer than five supernumerary arcs were visible at the inner edge of the primary bow, and these showed red only. I fancy that the phenomenon cannot be very rare, from the circumstance that in pictures of the rainbow red and yellow are frequently the only colours set down by the artist. A few months ago Mr. C. Brooke Branwhite of Clifton showed me a very beautiful sketch in oils by his father, the late Mr. Charles Branwhite, a colourist of no mean power, in which a beautiful and exquisitely pellucid rainbow was drawn with red and yellow tints only. It may also be mentioned that in the copy of Rafael's "Madonna di Foligno" in the Dresden Gallery, there is a semi-circular red and yellow rainbow. I have not seen the original Foligno Madonna in Rome; and should be interested to know whether in this also red and yellow are the only tints accorded by the colourist.

Haslemere House, Clifton SILVANUS P. THOMPSON

IN your issue of the 8th inst. (vol. xxiv. p. 431) your correspondent "A. M." describes what he calls a "pink rainbow" seen by him at Aldworth, near Haslemere, and as a painter I am interested in his description, as it exactly corresponds with the same phenomenon as seen by me here, same date, and viewed with curiosity by myself and friends.

Corrie Hotel, Arran, September 11 DAVID MURRAY

Atoms

ALTHOUGH I am not an "eminent" authority, perhaps you will excuse my troubling you with the following extract from a paper read by me before the Philosophical Society of Glasgow in November, 1875, a copy of which paper I posted to the Editor of NATURE:—"I have long been of opinion that the most probable hypothesis of the origin of atoms is that there is only one kind of matter—ether or its constituents—and that atoms are merely congeries of units of ether circling at enormous speeds round each other, differently grouped, in different numbers, at different velocities, and at different distances, even as the different members of our sun systems. . . . The numbers of units in each similar atom need not be always the same; a few dozens more or less will not be appreciable by us. On the other hand, if a so-called element show a plurality of spectroscopic lines or hues, I do not think it at all doubtful that there is a plurality of units moving to produce these, since they thus show effects of different modes of moving of bodies; all our different states of sensual consciousness of colours are necessarily dependent on differences in the modes of moving of the agents that excite in us such plurality of lines and hues. As the motions of atoms, or rather of groups of atoms, excite in us sensations of sound, so the motions of units, or rather of groups of units, excite in us sensations of colour, and of course the lower-pitched movements of dark heat. Then again, we may hold that the more lines that persist in a spark or a sun, the less easily reducible are the portions of the elements showing them, as far as these lines' constituents are concerned—the lines being still undissociated material." (*Proc. Phil. Soc. of Glas.*, vol. x. p. 61.) HENRY MUIRHEAD

Cambuslang, August 26

Luminous Phenomena on Rupture of Sea-Ice

IN my diary for January 20, 1881, occurs the following passage. I make no attempt to account for the phenomenon, but am certain it was not caused by any reflection of the lights on board the vessel:—

Digitized by Google

"Started from Christiania at about 2 a.m. in the *Nyland* steamer bound for Christiansand. At Krujero the steamer forced its way through the ice for half an hour till within about a mile of the land, where sleighs met it on the ice. The passengers and cargo were discharged or taken up on the ice, out of which we backed in close proximity to the *Kong Hacon*, which steamer had followed us in. A beautiful sunset and Arctic winter view, clear air, and rich sky, also a distant ship fast in the ice. The *Nyland* stopped at Arendal for the night, having got to the quay through much ice. We observe often phosphorescence or phosphorescence-like sparks and flashes in the ice as it is broken up by the steamer."

I think that the average thickness of the ice might have been about eight inches. I cannot give the temperature, but on the previous day at Christiania the thermometer indicated about 8° or 10° below zero Fahrenheit (about 40° Fahrenheit of frost). The diary from which the above extract is taken was kept jointly by myself and my travelling-companion, Mr. Winter, of the Indian Civil Service, who of course also saw the flashes referred to. I should like to have been able to talk the matter over again with him, but he is now in India. J. ALLEN ALLEN

[The question raised in this letter is a very interesting one. The phenomenon is possibly analogous to the electric flashes which are produced when loaf-sugar is crushed or when mica is rapidly split. It appears very improbable that it can be due to phosphorescent creatures in the water under the ice.—ED.]

Tidal Currents *versus* Wind Waves

IN NATURE, vol. xxiv. p. 286, a writer on "sea-shore alluvion" positively asserts that the travelling of sea beaches is due to wind-waves, and not to tidal currents, and calls a writer in the *Engineer* to task for having stated the latter. Notwithstanding this assertion, I would suggest that the writer in the *Engineer* is right. Twenty-five years ago, when an engineering student, I was taught that sea-beach travelling was due to wind-waves. Afterwards, while knocking about during fifteen years in the vicinity of the south and west coasts of Ireland, I noted facts that went to show that such a theory was not universally correct. This led me to study wind-action on the sea and lakes, also all I could find that had been written on the subject; the result being that as *good* evidence was so contradictory, no opinion could be come to from the evidence of others. But it was not till about ten years ago, when I was so circumstanced that I could properly study wave-action, and after six years' careful observation on the south-east coast of Ireland, that I found that tidal currents were the principal motive power; and on again reading what had been written on the subject, that I found that nearly all the advocates for the driftage of sea beaches by wind-waves had studied on beaches *where the most continuous and powerful winds acted in conjunction with the flow-tide current.* As the results of my observations have been published in the *Proceedings* of the Royal Irish Academy, English and Irish Institutions of Civil Engineers, the Geological Societies of London, Dublin, &c., during the last six or eight years, it is unnecessary to repeat them here. I would, however, point out that when there are only wind-waves and no tidal currents, the beaches as a general rule are banked up, but do not travel (the writer in NATURE seems to have observed this, but does not appear to see the importance of it). This may be seen in the tideless Mediterranean, as pointed out by the late Dr. Ansted in his paper on the Lagoons at the Delta of the Rhone; it may also be seen in Malcombe, or any other bay where there is a "head of the tide" but no tidal current; and in the different freshwater lakes, when the wind-waves are the *only* motive power. But wherever there are tidal currents acting on a coast the beach must travel. Such tidal currents are those that most perplex the erectors of groynes. If there was only the travelling augmented by wind-waves, the erection of groynes would be very simple; but, as a general rule, they are most necessary where there are strong tidal currents (or conflicting currents) due to the regular "flow" tide, "half counter" tides, or "on-shore" tides; which conflicting currents, combined with the action of wind-waves, let them be direct or as "ground swells," make up all the "cutting-out tides." The greater the complications the greater the "cutting out," and the more ingenious have to be the groynes. "Fulls" accumulate with the wind-waves, but rapidly disappear when the wind ceases. I presume the writer of the article in question is aware that the greatest rise of tide and the least current is at the "heads of the tides," while the least rise and greatest current is at "nodal or hinge lines"; and I would be interested to know where permanent beaches accumulate in the latter localities from what I have seen those that form rapidly disappear when the wind ceases. G. H. KINAHAN

H.M. Geological Survey

Glaciation

IN NATURE, vol. xxiv. p. 364, I see a notice of a paper Dr. Woeikoff on the glacial climate, in which it is shown "the difference of mean temperature at the lower ends of glaciers (in different parts of the world) reaches fully 20°." This is to be expected. The extent of glaciation depends not at all on mean or on winter temperature, but chiefly on summer temperature. *Perpetual* snow means *summer* snow, so that summer temperature is what determines the extent of the snow-fields remaining unmelted in the summer, and consequently of the glaciers which are fed by the snow-fields. The extent of glaciation is also much influenced by the amount of snow-fall. All this is stated in Forbes's "Norway and its Glaciers."

JOSEPH JOHN MURPHY

Old Forge, Dunmurry, Co. Antrim

Yellow Glass in Fog

SOME years ago I was staying at an hotel on the Lake Constance. One morning a fog came on which completely obscured the opposite shore, but looking through a sheet of yellow glass, which formed the border of the window, I was able, to my surprise, to see it distinctly. I presume the yellow glass choked the blue rays reflected by the fog, just as a Nicol prism, held at the proper angle, chokes the rays reflected from the glass and enables us to see clearly the picture behind it. On my way home I stopped in Paris, and, happening to call on one of the principal opticians, mentioned the circumstance to him. He forthwith showed me a naval telescope provided with a cap at the eye end containing a yellow glass, which could be removed at pleasure. I should like to know if the same simple contrivance has ever been used in our own navy. R.

The New Museum of Natural History

IN your article on "The New Museum of Natural History" (NATURE, vol. xxiii. p. 549 *et seq.*) it is stated that the specimen of *Archæopteryx macrura* in the British Museum is headless. Will you permit me to draw attention to a nodule projecting from the slab in which the fossil lies, which bears a striking resemblance to the cerebral portion of a bird's skull? It is some years since I visited the museum, but I recollect feeling satisfied at the time that the nodule was the missing head, and worth disinterring from its surrounding slate. E. H. PRINCE

Calicut, July 31

[The nodule referred to by our correspondent is well known and has been frequently criticised. Mr. John Evans, D.C.L., F.R.S., drew attention to it in an article published by him in the *Natural History Review*, 1865, pp. 415-421: "On portions of a cranium and of a jaw in the slab containing the fossil remains of the *Archæopteryx*." Although these fragments which occur in the slab in question undoubtedly belong to *Archæopteryx*, yet, as stated in our article, vol. xxiii. p. 551, the original specimen described by Prof. Owen is headless, while the newly-discovered Berlin specimen has the head entire and fairly well preserved, and still attached by the neck to the trunk.—ED.]

On the Velocity of Light

IN view of the experiments of Young and Forbes on the velocity of light, and of the article published by Lord Rayleigh on the subject, it may not be out of place to state an error which seemed at the time too evident to require special notice in my paper "On the Velocity of Light," that if the velocity of red and of blue light in air differed by as much as one and a half per cent., the image of the slit which served as the source of light, instead of being white, would be spread out into a spectrum which could not fail to be observed. The total displacement in these experiments amounted to 133 millimetres; therefore, a difference of velocity of the red and the blue rays of one per cent. would necessitate a spectrum 2·4 millimetres in length

Digitized by Google

It is needless to say that no spectrum was observed. These facts appear to be utterly irreconcilable with the conclusion drawn by Messrs. Young and Forbes.

ALBERT A. MICHELSON

Schluchsee, Prussia, August 28

Salmon in Preserved Rivers

HAVING resided for some time lately near one of our salmon rivers which is at present preserved by a club, I have at different times had conversations with men who knew it before its so-called preservation. They all say that when they were allowed to fish when and how they pleased, the supply of fish was much better in regard both to size and quantity. They account for it in the following manner:—Firstly, when the river was free, the people living near used to make spawning-beds for the fish, by placing large stones across the river and throwing gravel where deficient, and where gravel was naturally they used to loosen it with forks and remove the large stones. Secondly, they used to watch the fish at spawning time, and catch and kill all very large fish, say about 15 to 30 lbs. weight, after they had partially or wholly finished spawning, as they say the large fish destroy the salmon fry. Neither this nor the formation of spawning-beds is done at present. Would the above reasons account for the diminution in the size and number of salmon caught in our rivers? The diminution, in the river I speak of, cannot be accounted for by pollution, as the number of houses near enough to send their drainage into the river is too small to affect it, and as the river has a very quick fall and rocky bed, it is subject to such very rapid rises and falls in quantity of water that would prevent any settlement of noxious sediment.

F. C. S.

New Seismometer

IN NATURE, vol. xxiv. p. 113, there is a notice of a new seismometer which has several advantages claimed for it. Might I suggest what seems an obvious and important improvement? As a rule pendulums cannot record vertical or oblique motions, and yet these are often the most necessary and valuable to record. 1. To do this, and yet as easily allow of lateral registration, I would say, support a heavy (leaden) ball of some 100 lbs. by a 30 or 40 feet spiral or rubber spring of suitable strength. It will be found that a very considerable amount of vertical play can take place, especially vertical effort, ere the ball can be affected, and that lateral play of the support will produce very little effect indeed, unless, as is most unlikely, the motion is prolonged and is *continuous* in one direction. 2. Around the sphere, and at a very short distance from its surface, radial rods actuated like the key-plugs of a cornet are supported, say at every 30° all over the surface, contact with any one of which will electrically record *time*, and the pencil attached to the plunger record distance of stroke on revolving paper attached to plunger-tube.

Asam, July 6 S. E. PEAL

THE BRITISH ASSOCIATION

THE actual number of persons who attended the York Meeting of the British Association, as announced at the last meeting of the General Committee, was 2556; divided between 272 old life-members, 27 new life-members, 312 old annual members, 175 new annual members, 1232 associates, 514 ladies, and 24 foreigners. The seven previous occasions on which this number has been exceeded were:—Newcastle-on-Tyne, 1863 (3335); Manchester, 1861 (3138); Liverpool, 1870 (2878); Bath, 1864 (2802); Glasgow, 1876 (2774); Dublin, 1878 (2578); Aberdeen, 1859 (2564). The number fell below 1000 at Cambridge, Plymouth, Southampton, Ipswich, Hull, and Swansea. 1280*l.* were paid out by the Council for scientific purposes after the last meeting, a larger sum than on any occasion since 1873; while between 1873 and 1861 that sum was always exceeded, and at Norwich, in 1868, it amounted to 1940*l.*

The following foreigners were present at the meeting:—Professrs Barker of Pennsylvania; Bergeron, Paris; Bojanowski; Carbonnelle, Brussels; Chemin, Paris; Craig, Johns Hopkins University, U.S.; Dohrn, Naples; Eads, St. Louis, U.S.; Gariel, Paris; Dr. Asa Gray, Harvard University; Halphen, Paris; Dr. Edwin Hall, Baltimore, U.S.; Hubrecht, Leyden; Prof. W. W. Johnson, Annapolis, U.S.; Prof. O. C. Marsh, Yale College; Moser, Berlin; Prof. H. A. Rowland, Baltimore; Stephanos, Paris; Sturm, Münster, Westphalia; Prof. H. M. Whitney, Beloit College, Wisconsin, U.S.A.

We ought to have stated in our report of the doings of the Association in our last number, that Prof. Huxley's lecture on Palæontology, which we gave in the same number, was delivered on the evening of Friday the 9th.

Nearly 350 papers or reports were read before the several sections. Of these the Physical and Mathematical Section received 89; the Chemical Section 49; Geology 59; Biology 79; Geography 16; Economic Science and Statistics 26; and Mechanical Science 29. Of the papers in Section A 23 related to Electricity; 21 were Mathematical; Optics claimed 12; Meteorology 11; Astronomy and Physical Geography 12; Heat 5; and miscellaneous physical subjects 5. Of course prominent subjects of interest were electric lighting, electric measurements, and Faure's cells. Such subjects were thoroughly ventilated by discussions both in Section and Committee, and more intimately during the thousand and one opportunities for interchange of ideas which occurred in the afternoon and evening. Again, the storage of energy, the nature of meteoric dust, the existence of intra-Mercurial planets, the lunar disturbance of gravity, the nature of colours, and the contact theory were each severally discussed. Among the 49 Chemical papers several theoretical matters were introduced—specially the atomic theory, chemical nomenclature, vapour densities, molecular weights, Mendeleeff's law, and molecular attraction; processes of analysis and technical operations were described, and new experiments were explained. Of course a good deal of the geological work bore reference to Yorkshire, especially to the evidences of glacial action which it presents. The geological papers were of a very general and interesting character, and embraced every branch of the subject, from the vulcanology of Japan to the minerals found at Laurium, and from the Cheshire salt beds to the evolution of the Plesiosaurus. Section D furnished a larger number of papers than any other Section except A, but we must bear in mind that it really consists of three sub-sections, devoted respectively to Zoology and Botany, Anatomy and Physiology, and to Anthropology. The latter subject has developed extraordinarily, more than half the papers contributed to the Section were read before this Sub-Section. The report of the Anthropometric Committee, which evoked a good deal of discussion, was read in the Section of Economic Science and Statistics. In this section Mr. Grant Duff delivered a very able address, which was warmly received. A tendency to introduce matter which has a political bearing and which may be discussed from a political standpoint is sometimes apparent in this section, and should be carefully guarded against by the Committee. The Mechanical Section furnished some important reports on patent laws, wind pressure, tides in the English Channel, and the steering of screw steamers. Here also were papers on the different forms of electric lamp, the electrical transmission of force, and the illumination of lighthouses.

Thus it will be seen that all the prominent subjects of science have received their share of attention, and at the hands of one or other of the sections have been either expanded or discussed. The interchange of ideas has been incessantly going on, and many men have become acquainted who might otherwise have remained unknown to each other for years. Some 500 scientific men have been gathered together from various parts of the British Islands; and some 2000 persons have been brought face to face with the burning scientific questions of the day, and have had new interests awakened, or old knowledge resuscitated. There can be little doubt as to the

Digitized by Google

expediency of continuing the work of the Association, if it keep at all near to the standard of the York meeting. The German Society, founded nine years before our Association, and its prototype, still continues to meet annually; and scientific congresses are becoming more and more general every year in Europe.

Canada has been proposed as the place of meeting for 1885. The difficulties of time and place and expense are far less formidable than they appear at the outset. Great facilities would be put in our way by steamboat companies; and, once arrived, the Colony would receive us with open arms. Again, the Americans wish us to join their Association on some convenient occasion, and *àpropos* of this a practical American observed a few days since, "From the moment you set foot on American soil to the moment of departure, you should not put down a cent." One other fact remains to be noticed in regard to the York meeting. *Thirty-four* local societies and institutions were represented at the meeting by forty-nine delegates; and the Council have under consideration the conditions under which these delegates were present, and their object in attending. Cannot the Association do something for them? Cannot some organisation be introduced to influence the local societies through the Association, and cannot a committee of delegates be appointed to discuss matters connected with their respective institutions?

REPORTS

Report of the Committee, consisting of Dr. J. H. Gladstone, Dr. W. R. E. Hodgkinson, Mr. W. Carleton Williams, and Dr. P. P. Bedson (secretary), appointed for the purpose of investigating the Method of Determining the Specific Refraction of Solids from their Solutions.—Mr. P. P. Bedson, D.Sc., read the Report, and stated that the object of this report was to submit to further examination the method proposed some years ago by Messrs. Gladstone and Dale. According to this method the specific refraction of a solid may be deduced from that of a solution containing it, provided the specific refraction of the solvent is known, as also that of the solution and the composition of the solution. The experiments, of which an account is given in the report, appear to confirm this statement of the above-mentioned authors. The first case examined was that of liquid phenol. Its specific refraction for a ray of light of infinite wave-length was determined at 40° and 45°. The values obtained for the specific refraction of liquid phenol at 40° and 45°, viz., ·4850 and ·4848, are closely approximate to that obtained by Brühl (*Journ.* Chem. Soc., abst., 1880, p. 782) for phenol at 20°, viz., ·4862. Further, these results agree very well with the mean of the specific refractions obtained from the alcoholic and acetic acids solutions. The specific refraction of rock-salt in the solid state has also been determined and compared, with its specific refraction as deduced from its aqueous solutions; and it was found that the specific refraction obtained from the aqueous solution is substantially the same as that obtained from a prism of rock-salt. Further, the specific refractions of fused borax and boric acid have been determined, and in these cases also the specific refraction obtained from their aqueous solutions was found to be approximately the same as the specific refractions of fused borax and boric acid. The indices of fused borax and of fused boric acid were determined by means of prisms of these materials, which were cast in a mould of silver plates and afterwards ground and polished.

Report of Committee on Meteoric Dust, by Prof. Schuster.—This Committee was appointed for the double purpose of examining the observations hitherto recorded on the subject of meteoric dust and of discussing the possibility of future more systematic investigations. With regard to the first point we note that in a paper presented to the Royal Astronomical Society in 1879, Mr. Ranyard has given what appears to be a pretty complete account of the known observations as to the presence of meteoric dust in the atmosphere. It appears that in the year 1852 Prof. Andrews found native iron in the basalt of the Giant's Causeway. Nordenskjöld found particles of iron which in all probability had a cosmic origin in the snows of Finland and in the ice-fields of the Arctic regions. Dr. T. L. Phipson, and more recently Tissandier, found similar particles deposited by the winds on plates exposed in different localities. Finally, Mr. John Murray discovered magnetic particles raised from deposits at the bottom of the sea by H.M.S. *Challenger*. These particles were examined by Prof. Alexander Herschel, who agreed with Mr. Murray in ascribing a cosmic origin to them. For fuller details and all references we must refer to Mr. Ranyard's paper. There cannot be any doubt that magnetic dust, which in all probability derives its origin from meteors, has often been observed, and the question arises, in what way we can increase our knowledge on these points to an appreciable extent. A further series of occasional observations would in all probability lead to no result of great value, unless they were carried on for a great length of time in suitable places. Meteoric dust, we know, does fall, and observations ought if possible to be directed rather towards an approximate estimate of the quantity which falls within a given time. Difficulties very likely will be found in the determination of the locality in which the observations should be conducted. The place ought to be sheltered as much as possible against any ordinary dust not of meteoric origin. The lonely spots best fitted for these observations are generally accessible to occasional experiments only, and do not lend themselves easily to a regular series of observations. Nevertheless experiments continued for a few months at some elevated spot in the Alps might lead to valuable results. The Committee would like to draw attention to an instrument which is well fitted for such observations. It was devised by Dr. Pierre Miquel for the purpose of examining, not the meteoric particles, but organic and organised matters floating about in the air. A description, with illustrations, will be found in the *Annuaire de Montsouris* for 18[illegible]. Two forms of the instrument are given. In the first form, which is only adapted to permanent places of observations, an aspirator draws a quantity of air through a fine hole. The air impinges on a plate coated with glycerine, which retains all solid matter. By means of this instrument we may determine the quantity of solid particles within a given volume of air. The second, more portable, form does not allow such an accurate quantitative air analysis. The instrument is attached to a weathercock, and thus is always directed against the wind, which traverses it, and deposits, as in the other permanent form, its solid matter on a glycerine plate. An anemometer placed in the vicinity serves to give an approximate idea of the quantity of air which has passed through the apparatus. These instruments have been called aëroscopes by their inventor. It is likely that the second form given to the apparatus will be best fitted for the purpose which the Committee has in view.

Seventh Report of the Committee on Underground Water Supply, consisting of Prof. E. Hull, the Rev. H. W. Crosskey, Capt. Douglas Galton, C.B., Mr. James Glaisher, F.R.S., Prof. G. A. Lebour, Mr. W. Molyneux, Mr. G. H. Morton, Mr. W. Pengelly, Prof. J. Prestwich, Mr. James Plant, Mr. James Parker, Mr. T. Roberts, Mr. S. Stoke, Mr. G. J. Symons, Mr. W. Whitaker, was read by Mr. C. E. de Rance, of H.M. Geological Survey, the Secretary.—The Committee was appointed in 1874 at the Belfast Meeting of the Association, with Prof. Hull, LL.D., F.R.S., as Chairman, and Mr. De Rance, F.G.S., as Secretary and Reporter; its six published reports occupy 125 pages of the Society's *Proceedings*, and the results of the investigations of the Committee show that the Permian, Triassic and Jurassic formations of England and Wales are capable of absorbing from five to ten inches of annual rainfall, giving a daily average yield of from 200,000 to 400,000 gallons per square mile per day. The area occupied by these formations is, in round numbers, Permian and Trias, 8600 square miles, and Oolites, 6600 square miles, capable of yielding 1720 millions and 1320 million gallons respectively, at the lowest rate of absorption, or, united, a supply for 100 million people, at thirty gallons a head. Mr. De Rance then described the water-bearing condition of the Yorkshire area, and stated that the investigation would now be extended to all the porous rocks of South Britain.

Report on the Earthquakes of Japan, by Prof. John Milne.—The author arrives at the following conclusions:—1. That the actual back and forth motion of the ground is seldom more than a few millimetres (usually not equal to 1 m.m.), even though chimneys have fallen. 2. The motion usually commences gently, but is very irregular. 3. The number of vibrations per second usually vary between three and six. 4. During an earthquake shock *its direction* of motion may be irregular. 5. East and west vibrations, as recorded in Yedo, have in some cases been shown by time observations to have travelled up from the south. 6. Many of the shocks which visit Yedo appear to have come

Digitized by Google

from the district which is faulted, and which shows distinct evidence of *very recent* elevation.

Second Report of the Committee consisting of Prof. P. M. Duncan and Mr. G. R. Vine, appointed for the purpose of reporting on Fossil Polyzoa; drawn up by Mr. Vine.—The order is divided into three subdivisions :—

1. *Cheilostoma*, Bark. = *Celleporina*, Ehrenberg.
2. *Cyclostomata*, ,, = *Tubuliporina*, Milne-Ed., Hagenow, Johnston.
3. *Ctenostomata*, ,,

The following terms are used in this Report in describing the genera :—

ZOARIUM.—"The composite structure formed by repeated gemmation" = Polyzoarium and Polypidom of authors.

ZOŒCIUM or cell.—"The chamber in which the Polypide is lodged."

CŒNŒCIUM.—"The common dermal system of a colony." Applicable alike to the "Frond," or "Polyzoary," of Fenestella, Polypora, Phyllopora, or Synocladia: or to the associated Zoœcia and their connecting "interstitial tubuli," of Ceriopora, Hyphasmapora, and Archæopora, or species allied to these.

FENESTRULES.—The square, oblong, or partially rounded openings in the zoarium—*connected by non-cellular dissepiments*—of Fenestella, Polypora, and species allied to these.

FENESTRÆ applied to similar openings, whenever connected by the general substance of the zoarium—as in Phyllopora, Clathropora, and the Permian Synocladia.

BRANCHES.—The CELL-bearing portions of the zoarium of Glauconome, Fenestella, Polypora, or Synocladia; or the offshoots from the main stem of any species.

GONÆCIUM.—"A modified zoœcium or cell, set apart for the purposes of reproduction."

GONOCYST.—"An inflation of the surface of the zoarium in which the embryos are developed." Modern terms from the Rev. Thos. Hincks.

Report of the Committee on Erratic Blocks, drawn up by the Rev. B. W. Crosskey.—Many additional instances of the occurrence of erratic blocks were recorded. Particulars were given respecting granite and sandstone boulders found while excavating for the new dock at Maryport, Cumberland. The granite specimens vary in size from small pebbles to a ton in weight, and are rounded. The New Red Sandstone boulders vary from half a ton to two tons or more, and have sharp angles. The nearest granite occurs in the Kirkudbrightshire Hills, on the other side of the Solway, fifteen or twenty miles distant; on the New Red Sandstone is the stone of the district. A boulder of Shap granite found near Filey has been removed to the University Museum, Oxford. It rested on Oolitic strata at a height of about 150 feet above the sea. The nearest place where a granite of the same character is found is 108 miles distant, bearing west-north-west from Filey. The attention of the committee was drawn by Prof. T. McK. Hughes to a boulder of porphyritic hornblende diabase, near the centre of Anglesea. It is chiefly interesting as having been considered an inscribed stone, but the supposed characters are entirely due to rock structure. A detailed description of the great erratic called the "Holy Stone," at Humberstone, Leicestershire, was given. Its weight is about twenty-one tons. It rests on a denuded surface of the Rhætic formation. The height from which it travelled is about 400 feet above the sea, and is situated six miles north-west. The present height at which the block now rests is about 240 feet above the sea, and there is a river valley between these two points, running at right angles to the line of transit of the block, which is only 110 feet above the level of the sea. Various groups of boulders in Leicestershire were also described, some containing millstone grit blocks derived from Derbyshire, which must have travelled about thirty-five miles. A catalogue of 191 blocks in the parish of Ashwell, County of Hertford, was given. None of these blocks are local. Their general derivation is from the Oolites of the Midlands and from the Carboniferous and other rocks of more northern districts. The report concluded with an appeal to local observers to give assistance in cataloguing the rapidly-disappearing erratic blocks of the country.

Report on Thermal Conductivity of Certain Rocks, showing especially the Geological Aspects of the Investigations, by Prof. A. S. Herschel and Prof. Lebour.—This is the seventh and final Report of the Committee, and comprises a *résumé* of the results given in the preceding ones, with numerous additions and corrections. A bibliographical list of all papers on the subject, by Mr. J. T. Dunn, B.Sc., is given as an appendix. The apparatus and specimens employed during the investigations of the Committee are preserved in the museum of the College of Physical Science at Newcastle-on-Tyne.

SECTION A—MATHEMATICAL AND PHYSICAL

On the Possibility of the Existence of Intra-Mercurial Planets, by Balfour Stewart, LL.D., F.R.S.—It is a somewhat frequent speculation amongst those who are engaged in sun-spot research to regard the state of the solar surface as influenced in some way by the positions of the planets.

In order to verify this hypothesis observers have tried whether there appear to be solar periods exactly coinciding with certain well-known planetary periods. This method has been adopted by the Kew observers (Messrs. De La Rue, Stewart, and Loewy), who had an unusually large mass of material at their disposal, and they have obtained from it the following results :—

1. An apparent maximum and minimum of spotted area approximately corresponding in time to the perihelion and aphelion of Mercury.
2. An apparent maximum and minimum of spotted area approximately corresponding in time to the conjunction and opposition of Mercury and Jupiter.
3. An apparent maximum and minimum of spotted area approximately corresponding in time to the conjunction and opposition of Venus and Jupiter.
4. An apparent maximum and minimum of spotted area approximately corresponding in time to the conjunction and opposition of Venus and Mercury.

The Kew observers make the following remarks upon these results :—

"There appears to be a certain amount of likeness between the march of the numbers in the four periods which we have investigated, but we desire to record this rather as a result brought out by a certain specified method of treating the material at our disposal than as a fact from which we are at present prepared to draw conclusions. As the investigation of these and similar phenomena proceeds, it may be hoped that much light will be thrown upon the causes of sun-spot periodicity."

The Kew observers have likewise produced evidence of a different kind in favour of the planetary hypothesis, for they have detected a periodicity in the behaviour of sun-spots with regard to increase and diminution apparently depending upon the positions of the two nearer planets, Mercury and Venus. The law seems to be that as a portion of the sun's surface is carried by rotation nearer to one of these two influential planets, there is a tendency for spots to become less and disappear, while on the other hand, when it is carried away from the neighbourhood of one of these planets, there is a tendency for spots to break out and increase.

But whatever truth may be in these conclusions, it appears to be quite certain that periodical relations between the various *known* planets will not account for *all* the sun-spot inequalities with which we are acquainted. They may account for some, but certainly not for all. For there are solar inequalities of short duration which, presuming them to be real, can only be accounted for on the planetary hypothesis by supposing the existence of several unknown intra-Mercurial planets.

Indeed these short-period inequalities in sun-spots and the allied phenomena of terrestrial magnetism and meteorology have so augmented in number of late years as to make some observers inclined to question their reality; while others again resort to the above-mentioned hypothesis, and attribute them to intra-Mercurial planetary agency.

The method to be pursued in detecting the existence of inequalities will be easily understood by an illustration. Suppose that we had in our possession extensive records of the temperature of the earth's atmosphere at some one place in middle latitudes, and that, independently of astronomical knowledge, we were to make use of these for the purpose of investigating the natural inequalities of terrestrial temperature. We should begin by grouping the observations according to various periods taken, say, at small but definite time-intervals from each other. Now if our series of observations were sufficiently extensive, and if some one of our various groupings together of this series

Digitized by Google

should correspond to a real inequality, we should expect it to exhibit a well-defined and prominent fluctuation, whose departures above and below the mean should be of considerable amount.

Suppose, for instance, that we have twenty-four points in our series, and that we group a long series of temperature observations in rows of twenty four each, the time-distance between two contiguous members of one row being one hour. The series would thus represent the mean solar day, and we should without doubt obtain from a final summation of our rows a result exhibiting a prominent temperature fluctuation of a well-defined character, which we might measure (as long as we keep to twenty-four points) by simply adding together all the departures of its various points from the mean, whether these points lie above or below; in fine, by obtaining the area of the curve, which is the graphical representation of the inequality above and below the line of abscissæ taken to represent the mean of all the points. Suppose next that, still keeping to rows of twenty-four, we should make the time-interval between two contiguous members of a row somewhat different from one hour, whether greater or less, we should now in either case obtain a result exhibiting, when measured as above, a much smaller inequality than that given when the interval was exactly one hour; and it is even possible that, if our series of observations were sufficiently extensive, we should obtain hardly any traces of an inequality whatever.

In fine, when each row accurately represented a solar day, the result would be an inequality of large amount; but when each row represented a period either slightly less or greater than a day, the result would be an inequality of small amount. This process, as far as I have described it, is not new, inasmuch as something of this kind must be pursued in all attempts to detect inequalities. In the present instance we should by its means, after bestowing enormous labour in variously grouping, in accordance with a great number of periods taken at small intervals from each other, obtain definite results. These might be graphically represented in the following manner:—

The line of abscissæ might be taken to denote the exact values of the various periods, forming a time-scale, in fact, while the ordinates might represent the areas or summations obtained as above by employing these various periods. There would thus be in the case now used for illustration a very prominent peak, corresponding to twenty-four hours, which would fall off very rapidly on either side.

By means of the process now described we should at length, after enormous labour, obtain a graphical result, showing the exact position in the time-scale of the observed maximum inequality. In conjunction with Mr. William Dodgson, I have devised a method by which this labour is very greatly reduced, and the process so modified has been applied by us in order to determine whether there be inequalities of short period in the observed areas of the sun-spots occurring on the visible hemisphere of the sun. We have detected an inequality of this nature corresponding in period to 24·011 days, which, when subjected to a certain purifying treatment, appears to us to exhibit the marks of a true periodicity. But it has been suggested by Prof. Stokes that a method of this nature for detecting inequalities might with greater propriety be employed as a crucible for testing the value of some hypothesis introduced into it from without.

Acting upon this suggestion I have ventured to introduce the planetary hypothesis, and to ask whether the above sun-spot inequality of short period may not in reality be caused by an intra-Mercurial planet. It is quite easy to put this hypothesis to a test, taking for our guidance the results obtained by the Kew observers. For what do these results exhibit? In the first place they exhibit the probability of a sun-spot inequality corresponding to the period of Mercury round the sun; and in the next they exhibit the probability of similar inequalities corresponding to the synodic period of Mercury and Venus, and to the synodic period of Mercury and Jupiter.

Now if there be an intra-Mercurial planet of period 24·011 days, it will have the following synodic periods:—

With Mercury	...	33·025 days.
With Venus	...	26·884 days.
With Jupiter	...	24·145 days.

In conjunction with Mr. Dodgson I have applied the above method of analysis with the view of ascertaining whether there be well-marked sun-spot inequalities nearly corresponding to these periods, and we have obtained the following results:—

A very prominent inequality of period	...	32·955 days.
A very prominent inequality of period	...	26·871 days.
A less prominent inequality of period	...	24·142 days.

It will thus be noticed that there are prominent sun-spot inequalities, the periods of which agree very well with the synodic periods of the supposed planet with Mercury, Venus, and Jupiter, more especially if we bear in mind that this is only a first approximation.

The test, however, is not yet complete. Referring once more to the results of the Kew observers, it will be noticed that we have approximately maxima of sun-spot areas when Mercury and Venus, or when Mercury and Jupiter are in conjunction. Now if we assume that there is an intra-Mercurial planet of period 24·011 days, we are as yet unable to assign its exact position in ecliptical longitude at any moment. We know its period, and we may presume that it has considerable excentricity, but we know nothing else. We may, however, assume as most probable that the maximum point of the inequality of period 32·955 days corresponds to the conjunction of the planet with Mercury, the maximum point of the inequality of period 26·871 days to its conjunction with Venus, and the maximum point of the inequality of period 24·142 days to its conjunction with Jupiter. On this assumption, and knowing the average rate of motion of the planet in its orbit, we may deduce approximately its position at a given epoch independently from each of the three synodic periods above mentioned, and these positions ought to agree together, if our hypothesis be correct.

I have done this approximately, but am not able to bring exact figures before this meeting. The agreement is as great as can be expected, bearing in mind that we know only the average rate of motion of the planet, and not the variations of its rate, inasmuch as we are ignorant of its excentricity. I think I may state that three independent values of its position corresponding to January 1, 1832, will be obtained, and that the mean difference of a single value from the mean of the whole will probably not be more than twenty degrees. It would thus appear from this investigation that the evidence is in favour of the sun-spot inequality of 24·011 days being due to an intra-Mercurial planet. Of course a single research of this nature is insufficient to establish a theory of this importance, but as there are several short-period solar inequalities, the same method may be pursued for each, an operation which demands nothing but time and labour. It appears to me of great importance that these short-period solar inequalities should be systematically examined after this method.

The Effects of Gulf Streams upon Climates, by Dr. S. Haughton.—The author said that the Gulf Stream, and its counter current, the Labrador Current, produced important effects upon climate. The northern hemisphere was warmer than the southern from lat. 0° to lat. 30°, and it was colder than the southern from lat. 40° to 60°. The higher temperature of the southern hemisphere in the temperate latitudes was explained by the existence of three gulf streams in that hemisphere, while there was only one in the North Atlantic, and a partial one through Behring's Straits in the northern hemisphere. The general climatal effect of the Gulf Stream was therefore to make the annual range of temperature less, but it had no effect whatever upon summer heat, or upon the fruiting of plants and trees, that required a given July temperature for reproduction. The January temperatures in the North Atlantic at 70° were raised by the Gulf Stream, whilst the July temperatures remain unaffected. The effect of the cold currents, which were indirectly caused by the warm currents to preserve the proper condition of equilibrium, was nothing at all upon the January temperatures, but they lowered the July temperatures. The effect of the cold water was to lower the July temperature and to leave the January untouched, and the effect of the warm current from the south was to raise January and to leave July unaltered.

The Photographic Spectrum of Comet B 1881, by Dr. W. Huggins.—The author stated that in 1868 he applied the spectroscope to the light of comets, the result of his observations being to show the presence of carbon probably in conjunction with hydrogen in the cometary matter. Since then, until the present year, no comet of sufficient brilliancy to admit of observations being made had appeared. On the evening of June 24 last he directed the spectroscope to the head of Comet B with an exposure of an hour; and on the following night he obtained a second photograph with an exposure of an hour and a half. As it happened, the photograph which was the result of the longer period of exposure was the weaker of the two, but, taken together, an examination of the bands confirmed his

Digitized by Google

previous observations, and showed that part of the light of the comet was reflected sunlight and part original light; and further, that carbon was present in the cometary matter, with strong evidence also of the presence of nitrogen, in addition to carbon and hydrogen.

The Electric Discharge through Colza Oil, by A. Macfarlane, D.Sc., F.R.S.E.—The electrical properties of colza oil which I have examined are its dielectric strength and some phenomena which accompany the passage of the spark. By the dielectric strength of a substance I mean the ratio of the difference of potential required to pass a spark through air under the same conditions. The electrodes used were two parallel brass plates each 4 inches in diameter. When comparing the gases the standard distance of the plate chosen was 5 mm. In the case of liquids it is convenient to observe for a shorter distance, and reduce the result by the law which previous experiments of mine have established, namely, that in the case of the discharge between parallel plates through a liquid dielectric the difference of potential required is proportional to the distance between the plates (*Trans.* R.S.E., vol. xxix. p. 563). One set of observations gave the ratio for colza oil to be 2·7, another gave 2·5. Hence 2·6 may be taken. I have now obtained the following table of dielectric strengths for liquids (1 being unity).

Substance.	Dielectric Strength.
Paraffin oil	3·7
Oil of turpentine	4·0
Paraffin liquefied	2·4
Olive oil	3·5
Colza oil	2·6

The specific gravity of the colza oil is ·91. The passage of the spark was accompanied by the formation of gas bubbles, but there was no deposition of solid particles. As the 4-inch plates were placed horizontally in the oil a bubble produced by the discharge was prevented from escaping by the upper plate. When the upper plate is again electrified such a bubble behaves in the following manner. If it is large enough it will extend itself somewhat like an hour-glass between the plates, but if it is smaller it takes the form of an acorn with a flat base, the base resting on one or other of the plates. When the upper plate is charged positively the bubble is repelled so as to place its base on the lower plate; when the electricity is charged to negative the bubble remains with its base on the upper plate. A reversal of the order of charging did not change the effect. After a few electrifications a sufficient number of solid particles collect to form a chain, and thus interferes with the phenomenon, the bubbles then being lengthened out in a remarkable manner, but never repelled to the lower plate. When the upper plate was charged negatively, gas bubbles appeared to me to rise from the lower plate, as if they had been formed there. To test this point further I took some sparks between two smaller disks placed vertically in the oil. The gas-bubbles were observed to rise up at the negative surface as if they had been formed at the positive surface, and had been repelled or carried straight across, and then rose up at the negative surface. When the spark was taken between two points bent at right angles to two rods dipping into the oil, the bubbles were observed to shoot out in the direction from the positively charged point, and to circulate round the earth-rod some time before rising to the surface. These phenomena indicate that the bubble is positively electrified.

On the Electric Conductivity and Dichroic Absorption of Tourmaline, by Prof. Silvanus P. Thompson.—The electric conductivity of tourmaline differs in different directions; being, according to the author's experiments, a minimum along the optic axis. Tourmaline also possesses the optical property of dichroism, its absorption being a maximum for rays parallel to the axis, and greater for blue rays than for red, equal thicknesses of crystal being considered. According to the electromagnetic theory of light, bodies which are good conductors of electricity should be opaque to light. The author has in the August number of the *Philosophical Magazine* rewritten the equations of Maxwell's electromagnetic theory for the case of crystalline media possessing different conductivities in different directions. From these equations it appears that in tourmaline and negative uniaxial crystals electric displacements at right angles to the axis will be more absorbed than electric displacements parallel to the axis. This accounts for the well-known greater absorption of the ordinary ray, provided the views of Stokes and Fresnel are correct, that these displacements are at right angles to the so-called plane of polarisation. The difference of velocity between rays of different colour accounts for the difference of absorption being greater in that direction in which the conductivity is a minimum. It was also pointed out that in positive uniaxial crystals, in which the electric conductivity is a maximum along the axis, there will be maximum absorption of the extraordinary ray, and there will be least opacity along the axis. Smoky quartz and magnesic platinocyanide fulfil the latter condition. Specimens of tourmaline cut into cubes to show the colours in different directions were shown, and also specimens of magnesic platinocyanide and of herapathite. Mechanico-optical models were also shown illustrating the theory; a tourmaline being represented by a cube built up of layers of glass and wire-gauze. In conclusion it was shown that crystals in which the electric conductivity differs in three different directions will exhibit *trichroism*; and that di- or tri-chroic absorption is a general property of all coloured crystals other than those of the cubical system.

On the Application of Electricity to the Localisation of a Bullet in a Wound, by W. H. Preece.—The author showed how an electric current could be made an invisible and immaterial probe localising the position of a bullet in the human body without touching or giving the slightest sensation of pain. The conception of using electricity alone as the tool occurred to Prof. Graham Bell in Washington, who at once telegraphed to the author to consult him in reference to the use of Hughes' induction balance. In order to apply this apparatus to the localisation of a bullet in a wound, Prof. Hughes recommended that a pair of exploring coils should be made movable and portable, in order that they might be moved over the body of the wounded man. If the coils were brought within three inches of the bullet its presence could be detected, the direction in which the bullet was situated could be determined by observing the position of maximum sound, for in that position the bullet would be in a line with the axis of the coil. In order to ascertain the depth of the bullet a similar bullet is moved along in the direction of the axis of the other coil until neutrality is obtained; the depth of the trial bullet then will be equal to the depth of the buried one.

On the General Coincidence between Sun spot Activity and Terrestrial Magnetic Disturbance, by the Rev. F. Howlett, F.R.A.S.—The object of this paper was to inquire how far solar activity, more especially as regards sun-spots, is wont to be accompanied by terrestrial magnetic disturbances, as recorded by the automatic magnetic declination curves at Kew and Greenwich. The data for such an investigation were furnished by comparisons instituted between the most striking instances of sun-spots gathered out of a long series of solar observations carried on by Mr. Howlett from the year 1859 to the present epoch, and the synchronous conditions of the magnetic curves at the observatories above mentioned. The telescopic drawings of the spots were obtained with an achromatic of three inches aperture by Dollond, of forty-eight inches focal distance, projecting the sun's image on a large white screen in a darkened chamber. By employing a Huygenian eyepiece magnifying 120 linear, and placing the screen at the distance of five feet two inches from the eyepiece, a very distinct image of the sun was obtained of about five feet four inches in diameter, and of which every inch corresponded to just 30″ of the celestial arc. Not only were the measurements of all the solar phenomena rendered thereby exceedingly easy, but the conditions of amplification, illumination, and definition of details were combined in about the best possible manner for the observer's purpose, which was to maintain an accurate record of the solar spots, and very frequently of the faculæ also, on a large scale, and which have been collected into five volumes and presented to the Royal Astronomical Society. The comparisons commence with the very remarkable and cyclonic group of August, 1859, which was uniquely distinguished by the remarkable outburst of intense white light, far brighter than the photosphere itself, which fortunately was witnessed by the late Messrs. Carrington and Hodgson on the forenoon of September 1, but which Mr. Howlett missed seeing by only a few minutes, having completed his drawings, and left the telescope. Other striking and, if they may be so termed, crucial groups were compared with the magnetic records—very notably the great spot of October, 1865, engravings of which may be found in the volume of the *Proceedings* of the Royal Astronomical Society for the year last mentioned, as also the large groups of February, 1870, which were observed and drawn on the occasion of the recurrences by revolution of the same groups in the three consecutive months of February, March, and April of that year, and on the last of which months the total displacement, at one and the same time,

Digitized by Google

of the solar photosphere—or in other words, the total area occupied by the sun-spots—was no less than five thousand two hundred million square miles, or about twenty-seven times that of the superficies of the earth! So again in August and September, 1870, immense groups, occupying from four to five thousand million square miles, were observed to make two consecutive revolutions, and on the latter of which two occasions a beautifully enlarged photograph of the sun, twenty-four inches in diameter, was made by Mr. Titterton of Ely, under the auspices of the late Canon Selwyn, and exhibited to Section A. On all these occasions great magnetic disturbances, amounting often to absolute magnetic storms, were unequivocally manifested; and in fact out of twenty-four comparisons instituted, the following is the summary of results, as showing the coincidence of extensive solar activity and synchronous magnetic disturbances:—

Intensely	5	
Very decidedly	3	
Decidedly	9	= 21 affirmatively
Moderately	3	
Negatively (no spots, no storms) ...	1	
Questionable	1	
Contradictory	2	3 contradictory
	24	

Thus then, from the data collected, it would certainly appear that marked periods of solar activity are wont to coincide with marked periods of terrestrial magnetic disturbances; but yet from a careful comparison of the days and hours of the magnetic records appealed to, it also appeared that the disturbances were manifested in a variety of ways, not only as regarded the extent of the magnetic excursions of the needle, the rapidity of the oscillations, or the persistency of the more moderate disturbances, but also they were found to follow at considerably different intervals of time after the commencement of the observed solar outbursts. With respect, lastly, to reactionary influences, Mr. Howlett stated, on the authority of Mr. Whipple, the director of the Kew Observatory, that on the occasion of the perihelion passage of comet *b* 1881, on the 16th day of June last, the terrestrial magnetic curves were unusually quiescent.

On Artificial Flight, by Fred. W. Brearey.—The author proceeded to argue that the weight of the bird plays an active part in its flight, and that this result arises from the action of that portion of the pectoral muscle which depresses the wing. So great is the tension of this muscle that it is highly probable that, in the case of those long-winged and heavy birds which are able to fly without apparently moving a feather, the wings are kept extended against the resistance of the air underneath without any voluntary effort of the bird. Its weight pressing upon the air causes this muscle to expand in raising the wing, and aids in the effect of the downward stroke by its contraction. The author exhibited a model with wings 4 feet from tip to tip and 3 feet 2 inches from head to tail. The wings are moved by M. Penaud's plan of strands of india-rubber previously put into a state of tension, which in unwinding create a flapping of the wings. By an india-rubber cord attached to the under part of the wing and passing under the shaft to which the mechanism is attached an equilibrium between the two forces is attained; that is to say, the india-rubber strands are wound up to that extent that the wings in rising stretch the india-rubber cord—or, as the author calls it, the pectoral cord—until one force neutralises the other; so that, held in the hand, there is no action. When liberated, and committed to the pressure of the air, the weight of the model causes the wings to be elevated, and therefore stretches the pectoral cord, which in its contraction assists the power derived from the twisted rubber in depressing the wings against the weight of the model. During this action the flight is well sustained for 40 feet or more. The author states that an apparatus of the nature of a longitudinal parachute was liberated from a balloon which rose from Woolwich arsenal, and it travelled back, by the aid of gravity alone, to the arsenal, a distance of half a mile. From this he argued that if the fabric can be manipulated so that propulsion also can be imparted to it, then some encouraging results would be likely to follow. He showed a model of large size upon this principle, and how, by the action of the wing-arms, a wave is transmitted from head to tail along a loose surface in shape like a kite. This loose surface requires a fall before it can be inflated by the air underneath; the wave-motion of the wings is then found adequate to its propulsion.

On the Arrestation of Infusorial Life, by Prof. Tyndall.—Three years ago I brought with me to the Alps a number of flasks charged with animal and vegetable infusions. The flasks had been boiled from three to five minutes in London, and hermetically sealed during ebullition. Two years ago I had sent to me to Switzerland a batch of similar flasks containing other infusions. On my arrival here this year 120 of these flasks lay upon the shelves in my little library. Though eminently putrescible, the animal and vegetable juices had remained as sweet and clear as when they were prepared in London. Still an expert taking up one of the flasks containing an infusion of beef or mutton would infallibly pronounce it to be charged with organisms. He would find it more or less turbid throughout, with massive flocculi moving heavily in the liquid. Exposure of the flask for a minute or two to lukewarm water would cause both turbidity and flocculi to disappear, and render the infusion as clear as the purest distilled water. The turbidity and flocculi are simply due to the coagulation of the liquid to a jelly. The fact is some guarantee for the strength of the infusions. I took advantage of the clear weather this year to investigate the action of solar light on the development of life in these infusions, being prompted thereto by the interesting observations brought before the Royal Society by Dr. Downs and Mr. Blunt in 1877. The sealed ends of the flasks being broken off, they were infected in part by the water of an adjacent brook, and in part by an infusion well charged with organisms. Hung up in rows upon a board, half the flasks of each row were securely shaded from the sun, the other half being exposed to the light. In some cases, moreover, flasks were placed in a darkened room within the house, while their companions were exposed in the sunshine outside. The clear result of these experiments, of which a considerable number were made, is that by some constituent or constituents of the solar radiation an influence is exercised *inimical to the* development of the lowest infusoria. Twenty-four hours usually sufficed to cause the shaded flasks to pass from clearness to turbidity, while thrice this time left the exposed ones without sensible damage to their transparency. This result is not due to mere differences of temperature between the infusions. On many occasions the temperature of the exposed flasks was far more favourable to the development of life than that of the shaded ones. The energy which in the cases here referred to prevented putrefaction was energy in the radiant form. In no case have I found the flasks sterilised by insolation, for on removing the exposed ones from the open air to a warm kitchen they infallibly changed from clearness to turbidity. Four and twenty hours were in most cases sufficient to produce this change. Life is, therefore, prevented from developing itself in the infusions as long as they are exposed to the solar light, and the paralysis thus produced enables them to pass through the night-time without alteration. It is, however, a suspension, not a destruction, of the germinal power, for, as before stated, when placed in a warm room life was invariably developed. Had I had the requisite materials I should like to have determined by means of coloured media or otherwise the particular constituents of the solar radiation which are concerned in this result. The rays, moreover, which thus interfere with life must be absorbed by the liquid or by its germinal matter. It would therefore be interesting to ascertain whether, after transmission through a layer of any infusion, the radiation still possessed the power of arresting the development of life in the same infusion. It would also be interesting to examine how far insolation may be employed in the preservation of meat from putrefaction. I would not be understood to say that it is impossible to sterilise an infusion by insolation, but merely to indicate that I have thus far noticed no case of the kind.

The Sun-Spot Period and Planetary Tides in the Solar Atmosphere, by F. B. Edmonds.—The author said that the influence of the planet may be localised on a surface or stratum of small thickness, so that the disturbing force would vary as the square of the distance of the planet. Under this supposition the predominance of Jupiter seemed to shut out the idea that sun-spot maxima and minima could depend simply on the opposition and conjunction of the planets. The consequence of such a supposition was not to be lost sight of, but may be taken together with the more general supposition that the attractive force is exercised on a gaseous envelope, of which the altitude is not insignificant. Again, the mass of the sun is acted on by the planets, and such parts as are fluid, whether in the liquid or

Digitized by Google

gaseous form, are subject to a disturbance of a tidal character as a matter of course. The author argued that a disturbing body would therefore raise a tide on the sun more than one hundred times greater than the same force would raise it if acting on a globe the size of the earth, the other circumstances being the same. Looking at the sun-spot numbers as a record of spring tides and as a first approximation, recognising only such tides as would be due to the conjunction and opposition of Venus and the earth, it remained to establish a relation between these tides and the tide due to Jupiter in the form of special tides varying in magnitude with the sun-spot numbers.

On a New Integrating Anemometer, by H. S. Hele Shaw and Dr. Wilson.—An ordinary Robinson's cup anemometer is used to drive a train of wheels and thus ultimately a serrated roller, which moves a board in the direction of, and with a velocity proportional to, that of the wind. On the board, which is horizontal and about two feet square, is placed a sheet of paper, upon which the roller presses, and in turning leaves the required trace, at the same time moving the paper underneath it. The board is prevented from having a rotary motion by means of a pair of frames, the upper moving by means of wheels on the lower, each of which can only move in one direction, and these directions are perpendicular to each other. By a clockwork adjustment the time element is able to be introduced, which, taken in connection with space, gives velocity. A method of performing this was shown, as also a proposed form of the instrument for observatories.

On a Universal Sunshine Recorder, by G. M. Whipple.—The author gave a description of a new form of card-supporter for the Campbell sunshine recorder. It consisted of a light frame capable of holding the slip of cardboard, to be burned by the sun in any position. It was arranged so as to receive ordinary parallel strips of card at all times of the year, and to allow of the instrument being employed on any part of the earth's surface without detriment to its efficiency. The card-holders themselves are movable, so as to permit of the cards being changed indoors or dried, if wet, before removal, in order to avoid mutilating the record of the observation. The instrument also has an appliance for placing the card correctly in position to receive the sun's image.

On the Calibration of Mercurial Thermometers by Bessel's Method, by Prof. Rucker.—The author stated that the late Mr. Welsh of Kew Observatory described to the British Association in 1853 the methods which he introduced of making and correcting mercurial thermometers. The correction with which the author dealt was that due to the variations in the bore of the tube. Mr. Welsh's method of making this correction, which is still employed at Kew, is less theoretically perfect than others, and has been unfavourably criticised abroad. The author, in conjunction with Prof. Thorpe, has recently corrected a number of thermometers with great care by Bessel's method, which is the most elaborate and perfect hitherto proposed. One set of three thermometers were made for them at Kew, and were calibrated according to Welsh's method. Afterwards the measurements necessary for the application of Bessel's method were made by the Kew authorities, the calculations being performed by the author and Prof. Thorpe. The Kew thermometers were thus subjected to the most rigorous possible test, and they were able to announce that in one instrument the errors left after the application of Welsh's method were not greater than four-thousandths of a degree Centigrade, and in no case did they exceed one-hundredth of a degree. As it is impossible to read on these thermometers less than a hundredth of a degree with certainty, Welsh's method, as applied at Kew, is practically perfect.

SECTION B—Chemical Science

On a Process for Utilising Waste Products and Economising Fuel in the Extraction of Copper, by J. Dixon (Adelaide, South Australia).—This paper contains an account of a process for extracting copper from sulphurous ores, in which the heat generated by the combination of the oxygen of the air with the sulphur of the ore is utilised for the smelting of the ore. This process is based upon experiments, which, although the author regards as incomplete, show (1) that the charge grows visibly hotter by simply blowing air through it; (2) that the melting of the raw ore or regulus and its reduction can be carried on in the same furnace; (3) that if the ore is in lumps, and fed at the top whilst the air is admitted by the side, a practically clean slagg can be obtained; but if added in a coarse powder, as it is generally found in the market, it either blows out again or chokes the furnace; (4) that a rough copper of about 96 per cent. pure metal can be obtained by the successful working of this process.

On the Chemical Action between Solids, by Prof. Thorpe, Ph.D., F.R.S.—The author drew attention to the extremely rare instances of such action hitherto observed, showing how many of these might be explained on the supposition that combination actually occurred between the bodies either in solution or in a state of gas. For example, the formation of cement steel, by the combination of carbon with iron, which had long been adduced as an example of such combination between solids, was now explained by the fact that iron at a high temperature was permeable to gases, and that in the actual process of cementation oxides of carbon were formed, which were in reality conveyors of carbon to the metal. He then illustrated by experiments the formation of several compounds by bringing together the components in solid form, choosing as examples such as would manifest their formation by characteristic colouring. Thus, as instances, potassium iodide and mercuric chloride, potassium iodide and lead nitrate, and silver nitrate and potassium chromate, were powdered together in a mortar, and in each case evidence of an action was exhibited by the production of characteristic colours of the product of the reaction of these compounds. The author referred to the memoir of the Belgian physicist, Prof. Spring, on the same subject, some of whose experiments he had repeated and in the main confirmed. One of the most remarkable results obtained by the Belgian professor was the formation of coal from peat by subjecting the latter material to a high pressure. Peat from Holland and Belgium, when exposed to a pressure of about 6000 atmospheres, was, according to Spring, changed into a mass which in all physical characters resembled ordinary coal. Experiments of the same nature made by Dr. Thorpe with various samples of British peat yielded, however, a very dissimilar result. These experiments were made with pressures which were considerably less and more than those employed by Spring. Although solid, compact masses, hard and very much changed in structure, were attained, in no case was any product obtained which could be confounded with bituminous coal. He said it was highly improbable, on purely chemical grounds, that mere pressure had been little more than an important factor in the transformation of woody matter into coal.

Metallic Compounds containing Bivalent Hydrocarbon Radicals, Part ii., by J. Sakurai.—This is a continuation of the work, an account of which was given at the last meeting (NATURE, vol. xxii. p. 448, or *British Association Report*, 1880). *Dimercury methylene iodide*, $CH_2(HgI)_2$, is obtained by exposing methylene iodide with an excess of mercury to the action of light. It is a yellowish crystalline powder insoluble in ordinary solvents, but soluble in hot methylene iodide; it melts at 230° with partial decomposition. Iodine converts this compound into methylene iodine and mercuric iodide. This same compound is easily obtained by the exposure of the mono-mercuro-compound described last year (*loc. cit.*), mixed with mercury and mercuric iodide, to the sunlight. Hydric chloride reacts on dimercury methylene iodide, producing mercury iodomethide. The insoluble compound mentioned in the former publications (*loc. cit.*) the author regards $CH(HgI)_3$, and therefore contains a trivalent hydrocarbon radical. We have thus the following series of organo-mercury compounds:—

$$CH_3(HgI),\ CH_2(HgI)_2,\ CH_2HgI_2,\ \text{and}\ CH(HgI)_3.$$

On the Occlusion of Gaseous Matter by Fused Silicates at High Temperatures, and its Possible Connection with Volcanic Agency, by I. Lowthian Bell, F.R.S.

On the Siliceous and other Hot Springs in the Volcanic District of the North Island of New Zealand (with Photographic Illustrations), by W. Lant Carpenter, B.A., B.Sc., F.C.S. The author gives an account of his visit to this district in December, 1880; analyses of the water of many of the springs in the district are also given. The water of the springs in the neighbourhood of Lake Taupo were found to be chiefly siliceous; they are all more or less impregnated with free iodine, and possess a medicinal value. The water of one spring was found to be strongly impregnated with sulphates of iron and alumina. The water of the springs in the Hot Lake district of Rotona and Rotomahana contain large quantities of silica; the deposits from two of these form large siliceous terraces. The water of the springs in the White Island, which is the summit of an extinct volcano,

Digitized by Google

contains free hydrochloric acid in large quantities. The water of these springs deposits sulphur and sulphate of lime.

On the Two First Lines of Mendeleeff's Table of Atomic Weights, by W. Weldon, F.R.S.E. The author draws attention to certain relations exhibited by the fourth and eighth powers of the atomic weights of the elements in these two lines of Mendeleeff's series. The atomic weights used to exhibit these relations differ but slightly from those generally accepted. The fourth powers of the atomic weights of the elements from lithium to fluorine, viz. lithium, beryllium, boron, carbon, nitrogen, oxygen, and fluorine, are, with the exception of carbon, related to one another as the whole numbers 1, 3, 6, 16, 27, and 54. In order to establish a similar relationship for the atomic weight of all these elements, it is necessary to raise their atomic weights to the eighth power; when the following relationship is found to exist:—

$$Li^8 = 1N^8 = 2^8$$
$$G^8 = 3^2 \qquad O^8 = 3^6$$
$$B^8 = 3^2 \times 2^2 \qquad F^8 = 3^6 \times 2^2$$
$$C^8 = 3^2 \times 2^3$$

Similar relationships are established for the fourth powers of the atomic weights of the elements in the next line of Mendeleeff's table. The author concludes that, in the case of each of these fourteen elements some power of their atomic weight is a simple multiple of the corresponding power of the atomic weight of lithium; further, that this multiple is a function of 2 or 3, or of 2 and 3 combined.

Note on the Chrome Iron Ore of Japan, by E. Divers, M.D.—This paper contains a description and analysis of a specimen of chrome iron ore found in serpentine rocks, in the prefecture Oita. Analysis shows it to contain magnesia, replacing ferrous oxide, and the formula $MgO2FeO.2Cr_2O_3$ is attributed to it.

On the Oxides of Manganese, by V. H. Veley, B.A.—The author at the outset gives an historical sketch of the researches on this subject, in order to show how far it has been satisfactorily proved by them—(1) that manganese forms a series of definite oxides (apart from those present in manganic and permanganic acids); (2) that manganese dioxide forms a series of dioxides. An account is also given of the researches of Dittmar, Wright, and others on the conditions of formations of these oxides, and their behaviour when heated to various temperatures in certain gases. The author has studied the action of air, oxygen, nitrogen, and hydrogen at temperatures varying from 60°-200°, on an oxide having the formula Mn_6O_{11}. Hydrates of the following higher oxides, $Mn_{24}O_{32}$, $Mn_{24}O_{41}$, $Mn_{24}O_{45}$, $Mn_{24}O_{46}$, $Mn_{24}O_{47}$, have been prepared and analysed. When these oxides are heated in air or oxygen, at low temperatures, two changes are observed: (1) a loss of water of hydration; (2) an absorption of oxygen. When heated in nitrogen they are dehydrated, and at higher temperatures lose available oxygen. Heated in hydrogen, they are simultaneously dehydrated and reduced. The author regards these oxides as distinct chemical entities, and not mere combinations of molecules, or molecular compounds.

On the Inferences deducible from High Molecular Weights as exhibited by the Oxides of Manganese, by Prof. Odling, M.B., F.R.S.—In the course of his remarks Prof. Odling brought under the notice of the Section the various considerations which affected the determination of the relative weights of the reacting units of chemical substances. He contended that estimations of vapour-density had not had, and could not have, an absolutely determining influence, but thought these estimations always required to be checked by purely chemical considerations. In particular he referred to the cases of bodies which had two or more distinct vapour-densities—cases which were becoming added to daily. He expressed his entire concurrence with the views of the President of the Section as to the non existence of two distinct forms of combination, atomic and molecular, and strongly opposed the notion that various metallic elements possessed a definite capacity of saturation. He brought forward various illustrations to show that the saturation capacity of both metallic and non-metallic elements was indefinite. He contended that the doctrine of atomicity furnished a very inadequate idea of the most important facts of chemical combination, and that the representation of atomicity notions by graphic formulæ was highly misleading.

On Peppermint Camphor (Menthol) and some of its Derivatives, by R. W. Atkinson, B.Sc. (Lond.), and H. Yoshida.—This paper contains an account of the determinations of the physical properties of menthol ($C_{10}H_{20}O$), menthone ($C_{10}H_{18}O$), menthene ($C_{10}H_{18}$), and those of a hydrocarbon, $C_{10}H_{16}$, which latter compound is obtained by the action of hydric iodide on menthol and subsequent treatment with caustic soda and metallic sodium. The authors also discuss the constitution of the above compounds.

Note on the Occurrence of Selenium and Tellurium in Japan, by E. Divers, M.D.—The author draws attention to the fact that the presence of these two elements has been observed in Japanese sulphuric acid, and considers it probable that these substances occur in material quantities in Japan.

Note on the Sodium Alum of Japan, by E. Divers, M.D.—An analysis is given of a specimen of this substance; it occurs as an efflorescence on decomposing sodium albite, which contains pyrites scattered through it. It is found in the province of Idzumo, in the prefecture of Shiniané, near the coast. It is said to occur in considerable quantities. It occurs in two forms, one massive, finely fibrous, greyish white and translucent, and the second in friable opaque tears, slightly coloured by iron oxide.

Brewing in Japan, by R. W. Atkinson, B.Sc. (Lond.).—The Japanese brewing process is divided into two parts comparable with the malting and brewing processes of beer-making. The mode of preparation and the properties of the diastatic materials are different in the two cases. The Japanese equivalent for malt or "köji" hydrates maltose in addition to cane-sugar, dextrin, and starch, and the ultimate products of its action on starch-paste are dextrose and dextrin, or perhaps dextrose alone. Köji differs from malt in being rendered inactive by heat at a much lower temperature than malt. Köji is prepared as follows: a mixture of steamed rice and water is allowed to remain in shallow tubs at a low temperature (0°-5° C.) until quite liquid, it is then heated, fermentation commences, and continues until nearly all the dextrine first formed is exhausted. This product is now used like yeast, and is added to fresh quantities of steamed rice and water, fermentation proceeding until the percentage of alcohol amounts to about 13 or 14 per cent. by weight. After the greater part of the rice added has been used up, the mash is filtered and clarified by standing. The "sake" so produced requires very careful watching, and when summer approaches, or it exhibits signs of putrefactive fermentation, it is then heated in iron vessels; this operation has frequently to be repeated. Analyses of various specimens, fresh and diseased, are given in the paper.

Observations on the Specific Refraction and Dispersion of Light by Liquids, by J. H. Gladstone, Ph.D., F.R.S.—The general conclusions arrived at from a large series of observations on different liquids are as follows:—

I. The confirmation of the statement made by the Rev. T. P. Dale and the author, viz., that the length of the spectrum (the difference between the refraction of the Fraunhofer lines A and H) decreases with elevation of temperature.

II. It would appear that the length of the spectrum divided by the density, *i.e.*, $\frac{\mu H - \mu A}{d}$, is approximately, but not exactly, constant for different temperatures.

III. The specific dispersion appears to decrease with increase of temperature.

IV. The specific dispersion is influenced by the chemical constitution of a compound. In the case of hydrocarbons the change of the refractive equivalent of the carbon from 5·5 to 6·1 or 8 influences the specific dispersion to a far greater extent than the specific refraction.

V. Finally, the specific dispersion of a compound does not appear to be the means of the specific dispersions of its constituents.

On the Production of Crystals by the Action of Metals on Carbon Disulphide in Sealed Tubes, by P. Braham, F.C.S.—The author described a series of experiments which consisted in sealing up fifteen different metals in carbon disulphide. Some of these tubes were sealed up in 1879, and in those which contained gold, antimony, and bismuth, microscopic crystals were found. The composition of these crystals has not as yet been determined. The author also exhibited a micro-goniometer.

On the Alleged Decomposition of the Elements, by Prof. Dewar, M.A., F.R.S.—In his remarks Prof. Dewar dealt chiefly with the spectroscopic work from which Mr. Norman Lockyer had drawn conclusions very different from those of Professors Liveing and Dewar, especially concerning the value of evidence on the sun. Prof. Dewar argued that Mr. Lockyer's views regarding the existence of carbon vapour in the corona of the sun would not be scientific investigation, and that his views regarding the modifica-

Digitized by Google

tion of the spectrum of magnesium were equally illusory, and gave no proof of the decomposition of elementary substances. Finally he discussed Mr. Lockyer's theory of "basic lines," and addressed himself to a refutation of the same. The results recorded, he said, strongly confirmed Young's observations, and left little doubt that the few as yet unresolved coincidences either would yield to a higher dispersion, or were merely accidental. It would indeed be strange if amongst all the variety of chemical elements and the still greater variety of vibrations which some of them were capable of taking up, there were no two which could take up vibrations of the same period. They certainly should have supposed that substances like iron and titanium, with such a large number of lines, must each consist of more than one kind of molecule, and that not single lines, but several lines of each, would be found repeated with the spectra of some other chemical elements. The fact that hardly a single coincidence could be established was a strong argument that the materials of iron and titanium, even if they be not homogeneous, were still different from those of other chemical elements. The supposition that the different elements might be resolved into simple constituents and even into a single substance had long been a favourite speculation with chemists; but however probable that hypothesis might appear *à priori*, it must be acknowledged, according to Prof. Dewar, that the facts derived from the most powerful method of analytical investigation yet devised, gave it but scant support.

On Manganese Nodules and their Occurrence on the Sea-Bottom, by J. Y. Buchanan.—The author exhibited specimens of the nodules obtained from the South Pacific, and also from Loch Fyne; an account of those obtained in Loch Fyne was given in NATURE, vol. xviii. p. 628. Some nodules containing cobalt were also exhibited; these the author had obtained from New Caledonia. An account is given of the author's method of dredging for mud. The nodules have been found to contain iron oxides, copper, cobalt, nickel, sand, &c. Further, in no case was the amount of oxygen found to be sufficient to form a peroxide with the manganese. The kernels of these nodules are usually richer in manganese oxides than the external portions. Concerning their mode of formation the author thinks that this takes place *in situ*, and that the nodules are not brought from a distance. Further, it would appear that living organisms assist in this formation, although indirectly, insomuch as the decomposing animal matter reduces the sulphates of the sea-water to sulphides, which in their turn react on the iron and manganese minerals (chiefly silicates) in the mud, and thus forming sulphides of these metals. When the organic matter is exhausted these sulphides are oxidised to oxides by the oxygen of the water, forming concretions or incrustations of the ochreous oxides, which naturally inclose the other and unaltered constituents of the mud.

On the Action of Zinc, Magnesium, and Iron on Acidified Solutions of Ferric Sulphate, by Prof. T. E. Thorpe, Ph.D., F.R.S.—The extent of the reduction of the ferric salt may vary with the strength of the solution, with its temperature, with the amount of free acid present, and lastly with the specific nature of the metal employed. The author has studied the conditions under which the hydrogen does work as a reducing agent. Experiments were made on dilute solutions of ferric sulphate, containing known quantities of free acid. The author finds (1) that the extent of reduction, produced by a given weight of zinc in dissolving, increases with the temperature; (2) that it is also affected, although to a less degree, by the initial surface of the metal exposed. Whilst the extent of reduction, as also the rapidity of solution, increase with the temperature, at a given temperature the extent of reduction increases, although at a gradually diminishing rate, with the time of solution. The rapidity of solution and extent of reduction produced by a given quantity of zinc, of a given area and in a solution of a given temperature, and containing a definite weight of free acid, increase with the amount of reducible iron present. Experiments made by placing zinc in contact with platinum showed that, although the time of solution of zinc in contact with platinum is considerably diminished, as compared with that of zinc alone, little difference in the reducing effect is observed. Similar results were obtained with magnesium, although the amount of reduction is from one-fourth to one-third of that produced by zinc under similar conditions. The diminution of the rate of solution with decrease in the amount of free acid present, is far greater in the case of magnesium than in that of zinc. The author concludes that his experiments strongly support the view that the reducing power of nascent hydrogen is connected with the existence of this body in the atomic condition, since all conditions tending to prolong the duration of this atomic condition augment the reducing power.

On the Reducing Action of Zinc and Magnesium on Vanadium Solutions, by Prof. Roscoe, LL.D., F.R.S.—From his original experiments on this subject the author had drawn the conclusion that, whilst the reduction in the case of zinc and sodium took place from V_2O_5 to V_2O_2, in the case of magnesium it only proceeded to V_2O_3. Later experiments have, however, shown that each of these reducing agents acts in the same manner, but that the reduction from V_2O_5 to V_2O_2 takes place very slowly when magnesium is used.

Note on a New Method of Measuring Certain Chemical Affinities, by A. Tribe.—The author points out that when a metal is immersed in an electrolytic field, *i.e.*, in an electrolyte in the act of electrolysis, and the electromotive force set up on any part of its surface is sufficient to decompose the medium, then the positive *ion* separates out on that part of the surface which has received negative electrification, and the negative *ion* on the portion which is positively electrified. If such a plate be of a rectangular form, and it be so placed that the lines of force are perpendicular to its surface, then the maximum electromotive force is set up in the central part of the plate, and at the edges it becomes so weak as to be unable to initiate any electro-chemical action. If the sheet be placed in the electrolytic field, so that the lines of force are parallel with its sides and with two of its edges, then the maximum electromotive force is at the end of the plate and is the weakest at the centre, where it is unable to bring about electro-chemical changes. That this is the case is shown by the boundaries of the deposits, which in many cases are very sharply defined. From the intimate connection between electromotive force and chemical affinity, the author supposed that if, in a series of trials, the chemical affinities were altered, other circumstances remaining the same, the magnitude of the intermedial space between the boundaries of the electro deposits would increase with the force required to overcome the affinities of the *ions* of the electrolytes. This supposition has been confirmed by several experiments, *e.g.*, with sheets or analysers of silver immersed in solutions of chloride, bromide, and iodide of zinc, it was found that the intermedial space was the greatest in the case of the chloride, and in the case of the bromide it was greater than in the case of the iodide.

On some Phenomena of the Nature of Chemico-Magnetic Action, by W. Thomson, F.R.S.E.—The author had observed that the colour from a piece of cloth dyed with Prussian blue was discharged in the neighbourhood of a piece of iron which had been lying upon it for some weeks. The ash of the portions of cloth from which the colour had been discharged was found to contain but a trace of iron. Experiments were made in which no iron was used, and the blue colour was bleached but slightly, showing that the action could not be attributed to light alone. Further experiments, in which small pieces of iron or magnets were used, showed not only that the colour was discharged, but that the colour so discharged appeared to be rearranged in semicircles on each side of the bar of iron. When magnets were used, the colour assumed more or less of circular forms, which were developed not only from the poles, but from all parts of the magnets. These phenomena the author does not regard as due to magnetic action, for when a piece of gutta percha tissue was placed between the wet cloth and the magnet, no action took place, even after several weeks. Similar observations have been made with cloth dyed with aniline colours, and with a like result.

On the Double Iodide of Copper and Mercury, by Prof. Silvanus P. Thompson, D.Sc.—After describing the preparation of this compound, which is cuproso-mercuric iodide, Cu_2HgI_4, the author draws attention to one property, viz., its change of colour by a comparatively small change of temperature. At the ordinary temperature this substance possesses a brilliant red colour, and when heated, it becomes black, changing back to red on cooling. In thin layers this substance transmits light, but becomes opaque on heating. Now according to the electro-magnetic theory of light, opaque bodies are the best conductors of electricity; therefore this double iodide of copper and mercury should conduct heat better at a high than at a low temperature. Experiment has shown this to be true to a certain extent only, as beyond a certain temperature its conductivity becomes less; this is probably due to its decomposition when heated beyond a given temperature. In conclusion, the author pointed out several ways in which this change of colour of this

Digitized by Google

compound could be used in lecture experiments. For instance, it may be used to show the conduction of heat along a copper rod; for this purpose the rod is coated with the red compound, which is gradually blackened as the heat travels along the rod. It may also be substituted for wax in Tyndall's experiment for showing how crystals conduct heat. There are also a variety of other ways in which it may be applied.

The Effect of the Spectrum on Silver Chloride, by Capt. Abney, R.E., F.R.S.

Alterations in the Properties of Nitric Ferments by Cultivation, by R. Warington.—The author, after giving an account of his experiments on the cultivation of these ferments, which consist of organisms resembling bacteria, states that these nitrifying ferments are capable of existing in three forms—(1) the nitric ferment of soil, which converts both ammonium salts and nitrites into nitrates; (2) the altered ferment, which converts ammonium salts into nitrites, but fails to convert nitrites into nitrates; (3) a surface organism which converts nitrites into nitrates.

On the Fluid Density of Certain Metals, by Prof. W. Chandler Roberts, F.R.S., and T. Wrightson, C.E.—This is an account of a continuation of experiments upon this subject, some of which were submitted to the Section at Swansea (*vide* NATURE, vol. xxii. p. 448). The authors also exhibited the *oncosimeter* described in the *Journal* of the Iron and Steel Institute (ii. 1879, p. 418), by the aid of which these results were obtained. The following table contains the results obtained:—

	Sp. gr. solid.	Sp. gr. liquid.	Percentage of change in volume.
Bismuth	9·82	10·055	... Decrease 2·3
Copper	8·8	8·217	... Increase 7·1
Lead	11·4	10·37	... ,, 9·03
Tin	7·5	7·025	... ,, 6·76
Zinc	7·2	6·48	... ,, 11·10
Silver...	10·57	9·51	... ,, 11·2
Iron	6·95	6·88	... ,, 1·02

On Molecular Attraction, by F. D. Brown, B.Sc.—The author points out that, if we regard chemical affinity as neutralised by the union of two elements, we are then unable to account for the reactions taking place between molecules, and involving an interaction of the atoms composing different molecules. If, however, the act of combination be regarded as producing no change in the chemical forces, and it be supposed that the same attraction is exerted between any given pair of atoms without regard to the state of combination of one or both of the atoms, then a reasonable account can be given of chemical reactions, and the existence of molecular combinations does not appear very remarkable. Further, we are provided with a more or less effective explanation of the relative volatility of substances. Reasoning from this point of view, and considering the carbon compounds specially, the author concludes that intermolecular attraction should be greater in an acid than in a corresponding alcohol; greater in an alcohol of high molecular weight than in a homologue of which the molecule is less complex; greater in a primary alcohol than in the secondary or tertiary isomeride; and finally, greater in a chlorinated compound than in the corresponding substance containing hydrogen. If the volatility of a substance be a measure of the forces of attraction between the molecules, then it must be admitted that the boiling points of organic compounds show with some reason that the above expression represents the value of intermolecular attraction. From this point of view the study of the latent heat of many carbon compounds would materially aid us in the solution of the problem of chemical affinity.

On the Relative Atomic Weights of Silver, Manganese, and Oxygen, by Prof. Dewar, M.A., F.R.S., and A. Scott, B.A., B.Sc. The authors have determined the atomic weight of manganese, in relation to silver and oxygen, by a complete analysis of silver permanganate. Taking the atomic weight of silver to be 108, that of oxygen to be 16, the following values have been obtained for the atomic weight of manganese, 55·51, 54·04, 54·45. These numbers do not agree very well amongst themselves, nor with the numbers obtained from the analysis of pure manganese peroxide, made from manganese nitrate. By this latter method the following values were obtained, viz., Mn = 53·6 and 53·3.

Note on the Phosphates of Lime and Ammonia, by J. Alfred Wanklyn.—When ammonia is added to a soluble calcic phosphate a precipitate is obtained, which dissolves on heating, forming a viscid solution which solidifies on cooling. The soluble salt formed the author regards as having the composition $P_2O_5CaO(NH_4)_2OH_2O$. The author confirms Morfit's observation, that bone earth dissolved in acid is reprecipitated by alkalies in the form of a hydrated tribasic phosphate; a fact which he considers of great importance to agriculture.

On the Separation of Hydrocarbon Oil from Fat Oils, by A. H. Allen, F.C.S.—The author pointed out that the extensive production of hydrocarbon oils and their cheapness had led to their being employed for the purpose of adulterating animal and vegetable oils. Indications of their presence are afforded by the determination of the density of the oil, by the lowering of the flashing point and boiling point, further by its taste and the odour produced on heating. An oil so adulterated is not completely saponified, and the hydrocarbon oil may be removed from the product of saponification by extraction with ether. Fluorescence is also to some extent a useful indication of the presence of such a mineral oil; the fluorescence of some mineral oils may, however, be destroyed by chemical means, and some mineral oils are not fluorescent the absence of fluorescence in an oil does not therefore indicate the absence of a mineral oil.

On Bowdoïn's New Thermograph, by W. Lant Carpenter, B.A., B.Sc., F.C.S.—This is an instrument for recording changes of temperature, which are measured by the action of heat upon a hollow circular metallic ring connected with a circular vessel, the whole being filled with fluid and hermetically sealed. One end of the ring is fixed, the other is free to move, and its motion is magnified by a series of levers, to the end of which is attached a recording pen. Increments of heat cause increments of pressure in the ring, which moves at its free end. The instrument has hitherto been used for clinical purposes only, but the author thinks it might with advantage be used in chemical and physical researches.

The Blowing Wells near Northallerton, by T. Fairley, F.R.S.E.—The author gave an account of a series of observations on these wells, of which there are three in the neighbourhood of Northallerton. The gas issuing from the fissures of these wells has been analysed, and is apparently nothing more than common air.

On the New Metal Actinium, by J. L. Phipson.—The author stated that he had been able to separate a new element from the pigment zinc-white. The oxide of the new element is said to be slightly soluble in caustic soda, and is soluble in ammonia and ammoniacal salts. Its colour is uninfluenced by exposure to light. The sulphide of actinium is described as a pale yellow canary-coloured substance; it is insoluble in ammonia and soluble is soluble in acetic acid, and becomes darker on exposure to the air.

On some Vapour-Density Determinations, by Prof. Dewar, M.A., F.R.S., and A. Scott, B.A., B.Sc.—The authors described the apparatus they employed for the determination of the vapour-densities at high temperatures, and the means adopted for examining the vapours to ascertain whether or not decomposition had taken place. The vapour-densities of the halogen compounds of several metals have been determined, and it is interesting to note that the authors find, according to the vapour-density, the molecular formula for ferrous chloride is $FeCl_2$.

Some Remarks on Crystallogeny, by Prof. J. P. Cooke (Harvard University, U.S.A.).

On a New System of Blow-pipe Analysis, by Lieut.-Col. Ross.—The author described his system of blow-pipe analysis, and exhibited a compact form of blow-pipe and other necessary apparatus for use when travelling.

On Experiments with Manures on Barley Crops, Season 1881, by Tyson Macadam, F.C.S.—The author gave a detailed account of his experiments on two fields sown with barley in April of this year. The previous rotation of crops was as follows:—in 1878 potatoes with 20 tons of farmyard manure per acre, and 4 to 5 cwt. of dissolved manure; in 1879 wheat no manure; in 1880 turnips, 20 tons per acre of town sewage and 5 to 6 cwt. of dissolved manure. The only difference between the two fields was that in one case the turnips were carted off, whilst in the other they were eaten on the ground by sheep. From the time when the barley appeared to the time of cutting determinations of the following points were made every week: (1) the weight of the plant; (2) length of straw; (3) rate of storage of saline matter by the plant; (4) amount of water, nitrogen (given as ammonia), organic and vegetal matter; (5) the amount of the various saline ingredients present in the ash. The results appear to show that, in the case of the field where the turnips had been eaten on the ground, the barley grew more rapidly and was more healthy than that on the other field.

SECTION C—GEOLOGY

On the Laurentian Beds of Donegal and of other Parts of Ireland, by Prof. Edward Hull, LL.D., F.R.S., &c., Director of the Geological Survey of Ireland.—After a perusal of the writings of previous authors, and a personal examination made in the spring of 1881, in company with two of his colleagues of the Geological Survey, Mr. R. G. Symes, F.G.S., and Mr. S. B. Wilkinson, the author had arrived at the following conclusions:—1. That the Gneissose series of Donegal, sometimes called "Donegal granite," is unconformably overlaid by the metamorphosed quartzites, schists, and limestones which Prof. Harkness had shown to be the representatives of the Lower Silurian beds of Scotland (*Quart. Journ. Geol. Soc.*, vol. xvii. p. 256). This unconformity is especially noticeable in the district of Lough Salt near Glen. 2. That the Gneissose series is similar in character and identical in position and age with the "Fundamental Gneiss" (Murchison) of parts of Sutherlandshire and Ross-shire, and is therefore, like the latter, presumably of Laurentian age. That the formation is a metamorphosed series of sedimentary beds, has been shown by Dr. Haughton and Mr. R. H. Scott. 3. That the north-western boundary of the Donegal gneiss is a large fault between the Laurentian gneiss and the metamorphosed Lower Silurian beds, owing to which the older rocks have been elevated, and by denudation have been exposed at the surface. 4. That the Cambrian formation of Scotland is not represented in Donegal, and that the unconformity abve referred to represents a double hiatus, and is of the same character as that which occurs in Sutherlandshire, in the district of Fornaven and Ben Arkle, where the Lower Silurian beds rest directly on the Laurentian gneiss. 5. That Laurentian rocks may be recognised in other parts of Ireland, as in the Slieve Gamph and Ox Mountains of Mayo and Sligo, at Belmullet, and in West Galway, north of Galway Bay, where the rocks consist of red gneiss, horneblende rock, and schist, &c., similar to those in Donegal; also possibly in Co. Tyrone, as suggested by Mr. Kinahan.

Laurentian Rocks in Ireland, by G. H. Kinahan, M.R.I.A., &c.—The writer first mentioned that Cainozoic and Mesozoic rocks only occurred in the province of Ulster, while in the rest of the island there was a nearly continuous sequence of Palæozoic rocks, proved by the work of Griffith, Jukes, and their subordinates, from the Coal-Measures down to the Cambrian. He then pointed out that a recent attempt had been made to try and disturb their natural order, but that the new theory was solely founded on assertions that would not bear investigation. He proceeded to observe that the geologists of the pre-Cambrian school appeared to lay more weight on lithological evidence than that to which it was entitled, and in continuation he gave the localities for the oldest rocks in Ireland, with the reasons for and against the rocks being Laurentian. The localities are *Carngore*, or South-East Wexford, while it was shown that although the rocks were lithologically similar to the Laurentians, yet they contained Cambrian fossils—*Galway, South-East Mayo, Sligo, and Leitrim*—rocks that, from their lithological characters, were said to be Laurentian by Murchison, who recanted his statement when Harkness showed that stratigraphically this was an impossibility. These rocks occur on two zones, those on the highest being now said to be Laurentian—*Erris, North-West Mayo*—very old rocks, about which nothing can be positively said, except that they are older than the associated metamorphic rocks, also of uncertain age. *Donegal, Londonderry, and Tyrone*—the Laurentian age of some of these, years ago, was suggested by Jukes, while now it is positively asserted, but solely on lithological characters. The author pointed out that, although lithologically very like Laurentians, they were more like Huronians, Logan's description of the latter being very suitable for those of Donegal. He also pointed out that it was unnecessary to make vague assertions, as the stratigraphical position of the rocks ought to be easily worked out, either by starting from the Pomeroy fossiliferous rocks, or from the fossiliferous rocks found in Donegal by Dr. King; but that, at the same time, the work must be much better and more correctly done than that in the neighbourhood of Pomeroy, where the unaltered fossiliferous beds are classed with those they lie on, although the latter were extensively metamorphosed, contorted, upturned, and denuded, prior to the fossiliferous rocks being deposited on them. *North-East Antrim*-rocks, supposed to be of the same age as the older rocks near Pomeroy (*Upper Cambrians*).

On the Occurrence of Granite in situ about Twenty Miles South-West of Eddystone, by A. R. Hunt, M.A., F.G.S.—The author described and exhibited a fragment of granite brought up by a Brixham trawler twenty miles south-west of the Eddystone. He believed it to have been torn off a mass of granite *in situ*, and pointed out that in mineral composition it agreed with the gneisses of the Eddystone Reef and of the Shovel Reef in Plymouth Sound—all these rocks being composed of mica, quartz, and felspar, without hornblende or schorl. The author believed that the occurrence of gneiss in Plymouth Sound without altering the adjacent Devonian rocks was an indication that these Channel typical gneisses, and probably the typical granites too, were of pre-Devonian age.

Some Observations on the Causes of Volcanic Action, by J. Prestwich, M.A., F.R.S., &c., Professor of Geology in the University of Oxford.—The hypothesis generally accepted in this country as to the cause of volcanic action is that of the late Mr. Poulett Scrope, who considered that "the rise of lava in a volcanic vent is occasioned by the expansion of volumes of high-pressure steam, generated in a mass of liquefied and heated matter within or beneath the eruptive orifice," and that the expulsion of the lava is effected solely by high-pressure steam generated at great depths, but at what depths is not mentioned, nor is it explained how the water is introduced, whether from the surface, or whether from water in original combination with the basic magma. The objections to this hypothesis are—1. That during the most powerful explosions, *i.e.*, when the discharge of steam is at its maximum, the escape of lava is frequently at its minimum. 2. That streams of lava often flow with little disengagement of steam, and are generally greatest after the force of the first violent explosion is expended. 3. That it is not a mere boiling over, in which case, after the escape of the active agent—the water—and the expulsion of such portion of the obstructing medium, the lava, as became entangled with it, the remaining lava would subside in the vent to a depth corresponding to the quantity of lava ejected; but the level of the lava, *cæteris paribus*, remains the same during successive eruptions. Of the important part played by water in volcanic eruptions there can be no doubt, but instead of considering it as the primary, the author views it as secondary cause in volcanic eruptions. All agree in describing ordinary volcanic eruptions as generally accompanied or preceded by shocks or earthquakes of a minor or local character, to which succeed paroxysmal explosions, during which vast quantities of stones, scoriæ, and ashes, together with volumes of steam, are projected from the crater. The first paroxysms are the most violent, and they gradually decrease and then cease altogether. The flow of lava, on the other hand, which commences sooner or later after the first explosions, is continued and prolonged independently. Ultimately the volcano returns to a state of repose, which may last a few months or many years. Adopting the theory of an original igneous nucleus, the author considers a certain fluidity of the former, and mobility of the latter. The one and the other feebly represent conditions of which the phenomena of the rocks afford clearer and stronger evidence as we go back in geological time. Although thermometrical experiments, of the necessary accuracy and length of time, are yet wanting, it has been estimated that a small quantity of central heat still reaches the surface and is lost by radiation into space, and the escape of liquid lava and steam from volcanoes, and of hot springs from these and other sources, must bring, in however small a quantity, a certain increment of heat from the interior to the surface, where it is lost. This should lead to a certain contraction at depths, and of readjustment of the external crust, in consequence of which the fused masses of the interior will from time to time tend to be forced outwards, whenever tension became sufficient to overcome resistance. In this the author agrees with many other geologists. The further hypothesis respecting volcanic action, he now suggests, he has been mainly led to form by his researches on underground waters. A portion of the rain falling on the surface not only of permeable and fissured sedimentary strata, but also of fissured and creviced crystalline and other rocks, passes below ground, and is there transmitted as far down as the permeable rocks range, or as the fissures in the rocks extend, unless some counteracting causes intervene. Those causes are the occurrence of impermeable rocks, faults, and heat. The former two are exceptional, the latter constant. The increase of temperature with depth being 1° Fahr. for every 50 to 60 feet, the boiling point of water would be reached at a depth of about 10,000 feet, but owing to the pressure of the superincumbent rocks, it has been estimated that water will retain its liquidity and continue to

Digitized by Google

circulate freely to far greater depths. Unfortunately, very little is known of the substrata of volcanoes. Etna and Hecla apparently stand on permeable Tertiary strata, Vesuvius on Tertiary and Cretaceous strata, while in South America some of the volcanoes are seemingly situated amongst palæozoic and crystalline rocks. Under ordinary circumstances all the permeable strata and all fissured rocks become charged with water up to the level of the lowest point of escape on the surface, or if there should be an escape in the sea-bed, then to that level, *plus* a difference caused by friction. The extreme porosity of lavas is well known. All the water falling on the surface of Etna and Vesuvius (except where the rocks are decomposed and a surface soil formed) disappears at once, passing into the fissures and cavities formed by the contraction of the lava in cooling. Not only are these fissures filled, but the water lodges in the main duct itself, and occasionally rises to a height to fill the crater. Beneath the mass of fragmentary and cavernous volcanic materials forming the volcano, lies the original compact mass of sedimentary strata, &c. Owing to the fortunate circumstance of an Artesian well having been sunk at Naples, we know the underlying sedimentary strata there to consist of alternating strata of marl, sands, and sandstones, some water-bearing, others impermeable. The water from the lowest spring reached in this boring rose at first 8 feet above the surface, and 81 feet above the sea-level. Where the strata crop out in the sea-bed, the same pressure of the column of inland water forces the fresh water outwards, so as to form a freshwater spring in the sea, as at Spezzia and elsewhere on the Mediterranean coast. It is this fundamental hydrostatic principle which keeps wells in islands, and in shores adjacent to the sea, free from salt water, as in the Isle of Thanet. Where, however, the head of inland waters is small or impeded, sea-water will enter the permeable strata, and spoil the springs, as in the case of the Lower Tertiary sands at Ostend, and the Lower Greensand at Calais and in the Somme, in which latter department the underground spring was found affected to a distance of about one mile from the sea, but pure at a distance of nine miles. Further, if where the head of inland water is sufficient to force back the sea-water under ordinary conditions, those ordinary conditions are disturbed by pumping to an extent that lowers the line of water-level to below that of the sea-level, then the sea-water will flow inwards until an equilibrium is established. The flow of water under a volcanic mountain may be also influenced by the quaquaversal dip, which there is some evidence that the underlying strata there take, owing probably to the removal of matter from below, and the weight of the mountain. If we are to assume that the volcanic ashes and tufas below Naples are subaërial, the original land-surface has sunk not less than 665 feet, and a dip of the underlying strata from the seaward, as well as from inland, has in all probability been caused. This Artesian well was carried to the depth of 1524 feet, and passed through three water-bearing beds—one in the volcanic ashes, the second in the sub-Apennine beds, and the third in the Cretaceous strata at the bottom. No eruption of lava can then take place without coming in contact with these underground waters. The first to be affected will be the water in the cavities of the mountain in and around the crater. As the pressure of the ascending column of lava splits the crust formed subsequently to the preceding eruption, the water finds its way to the heated surface, and leads to explosions more or less violent. When the fluid lava breaks more completely through the old crust, and the mountain is fissured by the force and pressure of the ascending column, the whole body of water stored in the mountain successively flows in upon the heated lava, and is at once flushed off into steam. Then take place those more violent detonations and explosions—those deluges of rain arising from the condensed steam—with which the great eruptions usually commence. In conclusion, the author conceives that the first cause of volcanic action is the welling up of the lava in consequence of pressure due to slight contraction of a portion of the earth's crust. Secondly, the fluid lava coming into contact with water stored in the crevices of the masses of lava and ashes forming the volcano, the water is at once flushed into steam, giving rise to powerful detonations and explosions. Thirdly follows an influx of water from the underlying sedimentary or other strata lying at greater depths into the ducts of the volcano; and, lastly, as these subterranean bodies of water are thus converted into steam and expelled, the exhausted strata then serve as a channel to an influx of sea-water into the volcano. A point is finally reached when, owing to the cessation of the powerful shocks and vibrations, and the excessive drainage of the strata, the flow of the lava is effected quietly, and so continues until another equilibrium is established and the lava ceases to escape.

The Connection between the Intrusion of Volcanic Action, by Prof. W. J. Sollas, M.A.—In a volcanic eruption there are concerned first the elevation of the lava column in the axial pipe of the volcano, and next the explosion by which the lava is ejected into the air. The author attempts to find a *vera causa* for the latter. Sorby's researches on included cavities prove that steam at a high tension must have been everywhere present throughout plutonic rocks when these were in a state of fusion, and the presence of steam in ejected lava is well known. He considers it probable that the axial pipe of a volcano is occupied by fused rocks permeated by steam, which is probably in a liquid state, and the tension of which will depend on the hydrostatic pressure due to the lava column above it. Any sudden diminution of this pressure will tend to a sudden expansion of the steam, and tend to produce a volcanic explosion. The mere elevation of the lava in the volcanic pipe cannot directly produce a diminution of pressure, though an overflow at the surface of the ground would, but this infers that the overflow of lava should precede an eruption, which is not the case; hence the author concludes that an overflow of lava from the sides of the pipe into other places underground, and the pressure on the lava column being reduced beneath the point of overflow, an eruption follows. The ascendant pressure of intruded sheets and dykes of igneous rock known to occur beneath volcanic cones thus stands in close connection with the production of volcanic explosions.

A Restoration of the Skeleton of Archæopteryx, with some Remarks on Differences between the Berlin and London Specimens.—Prof. H. G. Seeley, F.R.S., traced the forms of the bones from a photograph, and arranged the skeleton so as to represent a bird which stood about ten inches high. The head has a post-occipital process in the cormorants; the neck is curved forward; the tail reached almost to the ground; and the limbs were exactly as in birds.

On Simosaurus pusillus (Fraas), *a Step in the Evolution of the Plesiosauria.*—Prof. H. G. Seeley gave a detailed description of the skeleton of Simosaurus recently discovered in the Trias near Stuttgart, and briefly noticed and figured by Dr. Oscar Fraas. He then drew special attention to the difference from Plesiosaurus, especially in the form of the pectoral arch and in the characters of the fore and hind limbs. The hind limb was discussed, to show how it might assume like character with the fore limb. Prof. Seeley concluded that the Plesiosaurs were originally land animals, and that their ancestors and affinities must be sought in Simosaurus, Nottosaurus, and allied types amphibious Triassic reptiles.

Influence of Barometric Pressure on the Discharge of Wells from Springs, by Baldwin Latham, M. Inst. C.E.—The author of this paper mentioned that it was alleged, by some of the long-established millers on the chalk streams, that they were able to foretell the appearance of rainfall from a sensible increase in the volume of water flowing down the stream before the period of rainfall. He had, therefore, undertaken a series of observations to investigate the phenomena, and he found, in setting up gauges in the Bourne flow in the Caterham Valley, near Croydon, in the spring of this year (1881), and selecting periods when there was no rain to vitiate the results, that whenever there was a rise of fall in the barometer, there was a corresponding increase in the volume of water flowing, and with a rise of the barometer, there was a diminution in the flow. The gaugings of deep wells also confirmed these observations; for where there was a large amount of water held by capillarity in the strata above the water-line, at that period of the year when the wells became sensitive and the flow from the strata was sluggish, that a fall in the barometer coincided with a rise in the water-line, and that under conditions of high barometric pressure the water-line was lowered. Percolating gauges also gave similar evidence, for after percolation had ceased and the filter was apparently dry, a rapid fall of the barometer occurring, a small quantity of water passed from the percolating gauges. The conclusion arrived at was, that atmospheric pressure exercises a marked influence upon the escape of water from springs.

On Evaporation and Excentricity as Co-factors in the Cause of Glacial Epoch, by the Rev. E. Hill, M.A.

On some Points in the Morphology of the Rhabdophora, by John Hopkinson.—The author, after reviewing the characteristics of the group, concludes from his investigation into the morphology of this group that they are the Palæozoic representatives of the recent Hydroida.

The Glacial Deposits of West Cumberland, by J. D. Kendall, C.E., F.G.S.—The extent, form, and inner nature of these deposits is first described; a number of new and important facts being brought forward on the distribution of boulders both in the boulder clays and in other glacial deposits. The conclusions arrived at from the facts are (1) that the boulder-clays were formed in the sea, partly by glacier action and partly by icebergs. The occurrence of boulders from distant localities, often in very different directions, in a matrix partaking of the character of the underlying rocks, is explained in an entirely new way. 2. That the middle sands and gravels are the result of marine and river action combined. 3. That the mounds of sands and gravels occurring in the mouths of valleys were accumulated by floating ice from pre-existing deposits. A somewhat novel explanation is given of the occurrence of boulders on higher levels than the rocks from which they were derived.

On "Flots," by J. R. Dakyns, M.A., Geological Survey of England and Wales.—The word "flot" is a miner's term for ore lying between the beds, or at certain definite horizons in the strata. In text-books flots are generally called "flats" or "flattings." They are of two kinds: (1) those connected with "cross-veins"; (2) those connected with courses of dun limestone. Firstly, cross-veins are veins (generally mere spar veins on Greenhow Hill) which cross and intersect or shift the metal veins, but which often bear ore at their intersection with the metal veins. Where these cross-veins cut the flot planes, ore is found. Secondly, similarly with courses of dun limestone. Dun limestone, so-called from its colour, is a dolomitised form of ordinary limestone. The dun lime occurs in beds or irregular masses, or more frequently in dyke-like courses, running north-north-west and south-south east. These courses are often several yards or even fathoms wide, and where the dun course crosses the flot plane ore is developed along the joints between the dun and the white limestones. Ore is not found along the flot plane except at its intersection with the cross-veins or with the courses of dun limestone.

On the Lower Cambrian of Anglesea, by J. McK. Hughes, Woodwardian Professor, Cambridge.—In this paper the author gives the results of further examination of the basement beds of the Cambrian, which he has now traced all along the north-west flank of the Archæan axis of Llanfaelog. The sequence he found almost invariably was in ascending order:—(A) Quartz conglomerate passing up into (B) grit, which in turn becomes finer, and passed into (C) sandstones weathering brown, which got split up in their upper part by thin slabby shales; (D) black shales with subordinate beds of black (D 2) breccia, and occasionally sandstone in the lower part.

On the Gnarled Series of Amloch and Holyhead in Anglesea, by T. McK. Hughes, Woodwardian Professor, Cambridge.—The author offers the results of his inquiries into the age of certain schists which form the main mass of the rocks of northern and Western Anglesea, leaving for the present the consideration of the masses of somewhat similar rock which occur south of the Llanfaelog gneissic axis in the central and south-east part of the island. The author believes these felspathic gnarled rocks must be either the marine equivalents of the Bala volcanic series, or the result of a later (probably Silurian) denudation of those beds. As Lower May Hill (= Birkhill) fossils only occur in the slates immediately south of the area in question, the latter supposition is the only one tenable in the present state of the evidence.

Notes on the Subsidences above the Permian Limestone between Hartlepool and Ripon, by A. G. Cameron, Geological Survey of England and Wales.—In this paper attention is drawn to the numerous forms of shrinkages of the land-surface, often extending to considerable depths into the rocks beneath, observable over the top of the Permian rocks betwixt Hartlepool and Ripon. As a general explanation of their origin, it is suggested that where the underground water, flowing over the limestone surface, reaches the margin of the sandstone, it receives a check whereby it accumulates, forming a chain of dams or pools along the line of junction of these rocks. As denudation proceeds, hollows form above, until ultimately the phenomena of the pits appear. This being so, "the water bubbling and frothing all over" is explained without calling in the aid of river-action. Allusion is made to the Home Farm Colliery accident at Hamilton, N.B., in February, 1877, through a subsidence in the gravelly alluvium of the Clyde; also to the recent subsidences at Blackheath, near London, and to the extensive caverns in the hematite districts of Furness.

The Great Plain of Northern India not an old Sea-Basin, by W. T. Blanford, F.R.S.—The author described the distribution of land in the Indian Peninsula and the intervention of a vast plain traversed by the Indus, Ganges, and Brahmaputra. This plain has constantly been considered, both by geological and lithological writers, as the basin of a great sea; but on examining the evidence, there does not appear to be a single fact in favour of the sea having at any geological period occupied the Gangetic or eastern position of the plain. The tract is evidently an area of depression filled up to above sea-level, through a long period of geological range of time.

The Gold-Fields and the Quartz Outcrops of Southern India, by William King, Deputy-Superintendent (for Madras), Geological Survey of India.—The paper is a *résumé* of the knowledge ascertained through the author's original survey of the Wainád gold-field in 1874 and by the later surveys and examinations of others; also in his examination of the Travancore and other areas in the beginning of the year. The geographical distribution of the gold areas is briefly treated of as being at Manyapet, on the Godávari River, near Dúmbal, in the South Mahratta country, near Kolár in Mysore, at Salem, in part of the Travancore State, and in the Nilgiri and Malabar country; and these are reduced to the more important fields of Malabar (including Wainád, and the Nilgiris) and Mysore. The reefs of Wainád are developed to a remarkable extent over a very large area of country; but their gold-bearing quality is only displaced over a portion of this, chiefly in the south-east of Wainád and in the adjacent low country of Malabar, in a generally east and west belt, the reefs outside of this being fewer and only very locally auriferous. The "leaders" or offshoots of the reefs in this belt are strongly and numerously developed, and they and the "casing" are rich in gold. The author expects the gold-yield to be seven pennyweights to the ton. He does not think that a paying return can be obtained on less than three pennyweights of gold to the ton.

Geology of the Island of Cyprus, by R. Russell, C.E.—The author described the physical features of the island as consisting of two great mountain chains, the axes of which are mainly parallel to each other, distinct from each other in structure and in physical matter. The southern range, rounded in outline, rises to 6340 feet; the northern range rises up from hummocky ground, on both sides, as it were, in one great continuous wall-like cliff. The central area consists of flat-topped irregular hills rising abruptly from the low ground, and therefore show more prominently than they would otherwise. The rocks which occur may be classified as follows:—

Post-Tertiary.	Blown sand.	
	Alluvium (vent).	
	Kavara (solidified surface).	
	Raised beach.	
	Sand and gravel (old river deposits).	
	Calcareous tuff and travertine.	
Tertiary.	Pliocene	Kerynia rock.
		Nicosia beds.
	Miocene	Idalian beds.
Secondary	Upper Cretaceous.	Konnos.
	Jurassic	Mount Hilarion limestone.
	Igneous rocks.	

The last upheaval of the island took place in a comparatively recent period, and was not more than fifteen or twenty feet in vertical height.

On some Sections in the Lower Palæozoic Rocks of the Craven District, by J. E. Marr, B.A., F.G.S.—The author showed by means of a thin band containing *Phacops elegans*, Boeck and Sars, that a series of beds consisting of pale green shales, underlain by black shales, passing below into a conglomerate which rested unconformably upon the Bala beds (the whole exposed in Austisich Beck, near Settle), were the equivalents of the Stockdale shales of the Lake District, and of the May Hill beds of the Continent. The beds are lithologically similar to those of the Lake District, and, like them, are surmounted by blue flags containing *Monograptus priodon* and *M. vomerinus*.

Life in Irish and other Laurentian Rocks, by C. Moore, F.G.S.—The author drew attention to certain forms found by a microscopic examination of specimens of certain Laurentian and other Palæozoic limestone prepared by trituration, solution in acid, and washing. These forms were clearly those of organic structures, some apparently hairs and other feather barbs. The author considered that he had taken precautions to eliminate

Digitized by Google

sources of error, through admixture of foreign materials, and he was led to think that the organisms belonged to the rocks.

The Subject-matter of Geology and its Classification.—Prof. W. J. Sollas, M.A., stated his object was to remove certain prevailing misconceptions as to the aim and scope of geology. The accepted definition of geology as "the history of the earth's crust and the fossils it contains," was considered to be both too wide and too narrow; the former since it includes palæontology, which, so far as it is a study of forms of life, belongs to biology; and too narrow, since the science of the whole, necessarily embraces much more than a study of its crust. Geology is one of the group of concrete sciences which include astronomy, geology, and biology. The scope of geology, or the science of the earth, is so wide, that a fresh classification of its subject-matter is required, and the author proposes *Morphological Geology*:—embracing geography, petrology, lithology, and mineralogy corresponding to anatomy and histology in biology; minerals, rocks, rock masses, constituting the earth's crust as cells, tissues, organs constituting living organisms, while palæontology is a study of successive morphological states, corresponding to embryology or development. *Physiological Geology*, considering the movement of the earth as a whole, and of all activities produced upon it, by extrinsic and intrinsic forces, acting singly or in combination; it rightly includes meteorology, hydro-geology, as well as the physiology of the earth's crust. *Distributional Geology* seeks to determine the distribution of the earth in time and space, and *Otiological Geology* corresponds roughly to what is known as cosmogony.

Exploration of a Fissure in the Mountain Limestone at Ravgill, by James W. Davis, F.G.S.—Attention was first called to this fissure by Mr. Tiddeman about eight years ago. It occurs in a quarry in Lothersdale, about five miles from Skipton. The mouth of the cavern is blocked with glacial drift; under this occurs a finely laminated clay, beneath which is a brown sandy clay with well-worn boulders. The fissure, when excavated, proved to be forty feet in length, horizontal, with a second branch, both of which are abraded and smoothened by the action of running water. Contains bones of *Elephas*, teeth of *Hippopotamus*, *Rhinoceros leptorhinus*, remains of the roebuck and hyæna, and one or two teeth of lion, and a single tooth of bear.

On the Zoological Position of the Genus Petalo-rhynchus, &c., *a Fossil Fish from the Mountain Limestone*, by J. W. Davis.—The species described resemble genera *Janassa*, Munst., and with it appear to occupy an intermediate position between the genera *Mylliobatis* and *Cestracionles*.

On Diodontopsides, Davis, *a New Genus of Fossil Fishes from the Mountain Limestone at Richmond in Yorkshire*, by James W. Davis, F.G.S.—These teeth resemble those of the modern fish Diodon.

Preliminary Remarks on the Microscopic Structure of Coal from East Scotland and South Wales, by Prof. Williamson, F.R.S., Owens College.—This subject will not be worked out until ten years, but he described layers of vascular tissue which can be separated layer by layer, while in other cases the charcoal layer on the surface of the coal and the organic structure is not capable of separation, and he stated that charcoal contains a tubular structure, like tissues of ordinary bark. The association of tissues resembles that of Cycadian plants; and referred to the genus *Cordaites* having been proved to belong to this group by M. Renault; the author has made nearly a thousand distinct observations on the structure of coal. Separates ordinary coal with large quantities of mineral charcoal, with macrospores of Lepidendroid plants filled up with myriads of microspores which were certainly not floated to the spots, from the *paraffine coals* which do not contain these large macrospores. He divides coals into "Iso-sporous" coals and "Hetero-sporous" coals; both abound in *Cordaites*, which form the mineral charcoal.

On an International Scale of Colours for Geological Maps, by W. Topley, Geological Survey of England.—The author described the objects of the International Geological Congress which is to meet at Bologna this month. Three main subjects are there to be discussed, (*a*) colours and signs for geological maps, (*b*) nomenclature of rocks and formations, (*c*) nomenclature of species. This paper is concerned only with the first of these questions, and especially with the resolutions passed by the English Map Committee, of which Prof. Ramsay is president, and the author secretary. At present all countries and many map-makers in each country have different systems of colouring maps, and it is necessary carefully to [illegible] or scale of colours used, before the maps can be [illegible]. The Congress proposes to [illegible] can be used and readily understood by all nations. [illegible] be possible, at least for some time to come, to [illegible] tion in national surveys in progress. But it is to be used for in new small-scale maps the scheme to be decided on will be adopted. One important point which the Congress [illegible] the preparation and publication of a general map of Europe, compiled under the authority of the Congress, from the various national surveys and the work of [illegible] observers. The scheme of colouring proposed is [illegible] on the order of colours in the solar spectrum, [illegible] the older rocks. Bright reds are reserved for [illegible] metamorphic rocks will be shown by dark tones [illegible] over the colour denoting the age; to these will be added bands of colour showing the period at which [illegible] has taken place, when such fact is clearly established; thus Silurian rocks metamorphosed in Cretaceous times would be shown by violet striped with alternate lines of dark purple and green. The sub-divisions of a formation will be shown by tints of the body colour, the darkest shade denoting the [illegible] division. The letter denoting the formation will be the initial letter of the name of the formation; with various arrangements one system of lettering can be made to [illegible] countries. It has been found impossible to adhere [illegible] order of colours of the spectrum, and an interposition has been made of browns and greys for the series of beds between the Silurian and the Lias. Examples of maps and reliefs [illegible] coloured according to the plan adopted were exhibited, as [illegible] also a series of Indexes of Colours to be used at various times by the Geological Survey, commencing with one in MS. by [illegible] la Bèche in the year 1832. The author also drew attention to the proposal made by Mr. J. W. Salter before this Association in 1847, and again at the International Exhibition in 1862, for a colour geological maps in the order of colours of the solar spectrum. The plan recommended by the English committee differs considerably in detail from that of Mr. Salter.

On the Rhætics of Notts, by E. Wilson, F.G.S.—The author gave a summarised account of the Rhætic series in Nottinghamshire. The Rhætic sections of this district already known to geologists comprise those at Gainsboro', Newark, and Bottesford. The author described several additional new sections of the Rhætics of the county—viz. at Cotham and Kilvington near Newark and Bottesford; at Barnstone, between Langford and Stathern; the boring for coal at Owthorpe, near Colston Bassett, and the section at Stanton-on-the-Wolds, between Keyworth and Melton Mowbray. A list of the Rhætic fossils of the district was given, and the presence of bone-beds noticed. The author could not agree with certain geologists that the green marls which are found beneath the Paper shales in Nottinghamshire, also the "Tea-green marls" of the West of England, belong to the Rhætic series, but took them to be Upper Keuper rocks, once red in colour, which had become discoloured by some [illegible] oxidising agent, probably carbonic acid evolved during the decomposition of the organic matters of the fossils of the Paper shales. For, in lithological character the green marls agree with underlying beds in the Keuper, but differed materially from the overlying Rhætics; then there was every appearance of a passage between the green marls and the underlying red marls of the Keuper; and, lastly, the green marls, with the rest of the Keuper marls, were practically unconformable, while with the commencement of the Paper shales we get the remains of an abundant and distinctly marine fauna, the Liassic.

Notes on the Cheshire Salt-Field, by C. E. De Rance, [illegible] of H.M.'s Geological Survey.—The author described the springs of the Keuper marls in Cheshire and part of [illegible] as having been derived from rainfall absorbed at the [illegible] original outcrop of the beds of thick rock-salt, which is represented by a porous bed. These waters flow out by [illegible] various natural springs, and are bored into by the [illegible] man shafts of the brine-pumpers. The natural solution of the rock-salt has caused the characteristic subsidences [illegible] the district. Northwich subsidences, however, have been caused by bad mining.

On the Strata between the Chillesford Beds and the Lower Boulder Clay. "*The Absidenley and Westleton Beds*," by J. [illegible] wich, M.A., F.R.S., Professor of Geology in the [illegible] Oxford.—The beds between the Chillesford Clay and [illegible]

Digitized by Google

Boulder Clay present such a series. Its exhibition on the coast of Norfolk, although very limited, is accompanied by special palæontological features that have caused it to be divided into the number of local beds which have been described by Trimmer, Green, Gunn, Wood, and Harmer, the author, Reid, Blake, and others. It includes the "Laminated Clays" of Gunn, the "Bure Valley Crag" of Searles-Wood, the "Westleton Shingle" of the author, and the "Rootlet-bed" and "Norwich Series" of Blake. Without reverting at present to the exact correlation of the several beds in the Norfolk area, respecting which there is still some difference of opinion, the author suggests that they should be included under a general term founded on the localities where, on the one hand, their varied palæontological characters are exhibited, and on the other where their peculiar petrological characters are well marked—characters which the author proposes to show, in another paper, have a very wide range, and serve to mark an important geological horizon in some interesting questions of local physical geology. The Mundesley beds were described by the author in 1860, and consist of alternating beds of clay, sands, and shingle, some containing freshwater and others marine mollusca, with a forest-growth and mammalian remains at their base; and again in 1871, including them in his Westleton group (No. 5 in the author's sections), which he showed to consist entirely of great masses of well-rounded shingle, with intercalated seams containing traces only of marine shells. Seeing the inconvenience of attaching the same term to the two very distinct series of beds, and that it may conflict with other local terms, the author now proposes to group this series under the term of "The Mundesley and Westleton Beds," indicative of their stratigraphical position in Norfolk, and of characters in Suffolk which serve to trace them in their range westward and inland to considerable distances beyond the Crag area, to which alone these beds have hitherto been restricted. At the same time it may be convenient, for brevity, to use one term only in speaking of typical cases.

On the Upper Bagshot Sands of Hordwell Cliff, Hampshire, by E. B. Tawney, M.A., F.G.S.—The descriptions of former writers having been cited, it was found that there were two main views regarding the affinities of these sands, which occur in the cliff between Long Mead End and Beacon Bunny. The view formulated by the distinguished foreign geologists, D'Archiac, Dumont, Prof. Hebert, and Prof. C. Mayer, is that they are parallel to the upper sands of the Beauchamp (= Barton) period, and allied, therefore, to the marine Barton beds. This view is much the same as that of E. Forbes, and the Geological Survey, who called them the Upper Bagshot Sands. Latterly Prof. Judd has sought to revive the term Headon-Hill Sands for them, presuming them to be most nearly connected with the Headon series, and extending the bounds of that series to receive them. The author now gives a list of twenty-eight species obtained from the bed at Long Mead End; of these 35 per cent. are common to the sand and the Barton beds, but do not occur in the Headon series; while only 21·4 per cent. are common to the sand and Headon series, but do not occur in Barton beds. It is shown that this sand belongs to the zone of *Cerithium pleurotomoides*, Lam., and is exactly parallel to the sands of Mortefontaine, which belong to the same horizon, constituting the upper portion of the Beauchamp deposits. This is altogether below the *C. concavum* zone. From these sands being intimately connected with the Barton beds in both areas, it is held that the term Upper Bagshot is the most fitting designation that has been proposed for them.

NOTES

THE Emperor of Germany has, by Imperial Decree dated June 1, 1881, awarded the Gold Medal of Merit for Agriculture to Mr. Lawes and Dr. Gilbert jointly, in recognition of their services for the development of scientific and practical agriculture.

THE death is announced, at the age of sixty-two years, of Mr. Frederick Currey, F.R.S., F.L.S. Mr. Currey was well known as a botanist, and was secretary to the Linnean Society from 1860 to 1880. It is stated that Mr. Currey has left his valuable collections of fungi to Kew.

THE honour of knighthood has been conferred upon Dr. G. C. M. Birdwood, C.S.I., of the India Office; and also upon Dr. John Kirk, H.M. Political Agent and Consul-General at Zanzibar, well known as the friend of Livingstone, and naturalist to his second exploring expedition, and as having done so much to promote African exploration.

THE Sedgwick Memorial Fund (Cambridge) now amounts from subscriptions and interest to more than 14,000*l.*, but this sum is not sufficient to build the new geological museum which it has been decided to erect in honour of the late professor. As, however, the present museum was built partly by subscriptions collected mainly through the exertions of Prof. Sedgwick, with a view to the erection of a geological museum, as well as of the library and other University buildings, the value of the portion occupied by the present museum should be taken into account in estimating the sum available for the new memorial building. An architect has been consulted as to the possibility of erecting a new geological museum and a chemical laboratory on the vacant space in front of the new museums and lecture-rooms facing Pembroke Street, but after examination of his plans and report it was found that the proposal could not be carried out, and it has consequently been decided to await the result of further negotiations for the purchase of the contiguous property. The recent acquisition by the University of some adjoining land will, it is hoped, diminish the difficulties now existing in the way of finding a suitable site for the erection of the new geological museum.

A LONG and interesting article in the *Daily News* of Tuesday describes the progress which has been made in carrying out the scheme of Mr. Holloway for the erection of a college for the education of young ladies. Mr. Holloway's endowment is of the amplest liberality; the building is all that could be desired, and is in a fair way of being completed; there is no danger of the institution becoming one for the benefit of the teachers and not of the students; the programme of education is meant to place science on a footing of absolute equality with learning. "The governing body will consist of twenty-one persons, to be appointed partly by the University of London, and partly by the Corporation of London, and it is stipulated that a certain portion shall always be women. Religious opinions are not in any way to affect the qualification for a governor. It is the founder's desire that power by Act of Parliament, Royal charter, or otherwise, should be eventually sought to enable the college to confer degrees after due examination; and that until such power is obtained the students shall qualify themselves to pass the Women's Examination of the London University, or any examination of a similar or higher character which may be open to women at any of the existing universities of the United Kingdom. The curriculum will not be restricted to subjects enjoined by any existing university. Instead of being regulated by the traditions and methods of former ages, the system of education will be mainly founded on studies and sciences which the experience of modern times has shown to be most valuable, and as best adapted for the intellectual and social requirements of students. The governors will therefore be empowered to provide instruction in any subject or branch of knowledge which shall appear to them, from time to time, most suitable for the education of women; and the curriculum of the college will not discourage students who may desire a liberal education apart from the Latin and Greek languages." All this is admirable, and we trust the spirit of the founder's wishes will be faithfully carried out. This building and the Sanatorium are not far from Virginia Water, and the total cost, with endowments, will probably amount to close upon a million.

IN connection with the Smoke Abatement Committee, an International Exhibition and trials of smoke-preventing appliances will be held in the East and West Arcades, and in buildings adjoining the Royal Albert Hall, at South Kensingto

Digitized by Google

from October 24 to November 26. Gold, silver, and bronze medals and certificates of merit will be awarded upon the report of a special committee. Regulations and forms of application for space may be had on application (by letter) addressed to Mr. Gilbert R. Redgrave, Superintendent of the Exhibition, Exhibition Buildings, Queen's Gate, South Kensington; or to Mr. W. R. E. Coles, Hon. Secretary to the Smoke Abatement Committee, 44, Berners Street, W.

THE Parkes Museum is closed until the end of September. In October it will again be opened free to the public on Tuesdays, Thursdays, and Saturdays, and during the winter lectures on sanitary science will be given in the Museum. The lectures will be illustrated with the sanitary appliances deposited in the Museum, which now include many new contributions sent from the recent Medical and Sanitary Exhibition at South Kensington. We believe it is intended to distribute the awards to the exhibitors at the Exhibition, at the second public annual meeting of the subscribers to the museum in October or November.

A NEW College of Practical Engineering has been opened at Muswell Hill, near London, under the auspices of a number of eminent practical engineers, among whom we may mention Sir John Anderson, late chief engineer at Woolwich, Sir Henry Bessemer, Sir R. M. Stephenson, Sir Joseph Whitworth, Bart., and Mr. Charles Manby, honorary secretary of the Institution of Civil Engineers. The principal of the College is Mr. John Bourne, C.E., author of several works on the Steam Engine and other kindred subjects. The instruction it is stated will combine the best theory with the best practice.

AS a special number of the *Journal* of the Society of Telegraph Engineers, a valuable Guide-Book to the British Section at the Paris Electrical Exhibition has been issued, edited by Prof. W. E. Ayrton, F.R.S.

THE success of the Siemens electrical railway in Paris is very great, and the mode of locomotion very highly prized by Parisians. It is certain that steps will be taken after the Exhibition for rendering it a permanent feature of the French capital.

DURING the recent meeting of the British Association a conference of delegates from scientific societies was held, and the chair was occupied by Mr. W. Whitaker, F.G.S., Norwich Geological Society. The following resolution was adopted:—"That a committee be appointed, consisting of Sir Walter Elliot, F.R.S., Mr. H. George Fordham, Mr. John Hopkinson, Mr. G. J. Symons, F.R.S., and Mr. W. Whitaker, to arrange for a conference of delegates from scientific societies to be held at the annual meetings of the British Association, with a view to promote the interests of the societies represented by inducing them to undertake definite systematic work on a uniform plan; that Mr. Fordham be the secretary, and that the sum of 5*l.* be placed at their disposal for the purpose." An interesting conversation followed as to the best methods of stimulating the local societies to more active work. Mr. John Hopkinson, F.L.S., F.G.S., gave a most interesting account of the operations of the Hertfordshire Natural History Society. He had induced several members to take up the registration of the rainfall, and they had now twenty-eight observers of rainfall in their small county. Every one did not care about such observations, but there were plenty of other matters needing attention. Other members had been induced to take up the recording of the migration of birds, the flowering of plants, the appearance of insects, and other periodical phenomena; and the club furnished about one-third of the entire phenological observers of the Meteorological Society. They were also preparing lists of the fauna and the flora of the county, and one ornithologist was collecting a record of all the birds that are, or have been, observed in Hertfordshire. A resolution was unanimously adopted appointing Sir Walter Elliot and Messrs. Fordham, Symons, and Whitaker a committee to arrange a Conference, and to send out a circular to the various societies pointing out the work of the various committees of British Association to which there might [illegible] scientific work of a systematic character that [illegible] undertake.

AT a recent meeting of the Bankside Natural History Society Mr. E. A. Walford read a note "On the Course of a Fire-ball at Watergall" on August 23. In answer to Walford's queries, Mr. Fessey, *jun.*, had sent an answer as follows, dated "Watergall, Leamington, August [illegible]. As regards the fire-ball, I was about 200 yards from it, in a field. I saw it directly it left the sky, as I was looking in the direction at the time. When I first saw it, it looked like a ball of fire, about as large as a dinner-plate. It [illegible] and I have no doubt I could have run [illegible] the time I first saw it until it struck the ground, [illegible] fifteen to eighteen feet from the ground, I [illegible] loud crash, quite as loud as a cannon, [illegible] thunder, which was very loud also. The explosion [illegible] whole buildings. I certainly thought the shell [illegible] but when it exploded one part struck the hedge, [illegible] in the ground about a foot deep, and laying all the [illegible] but not damaging them. For some time the place [illegible] fire, and there was a considerable quantity of [illegible] hit the ground, lasting for a second or two. [illegible] self and four men. They also agree with me that [illegible] as possible a correct explanation of it. We dug [illegible] yesterday, but found nothing. The soil was [illegible] several inches deep."

DR. C. S. MINOT, in a paper read at the Cincinnati meeting of the American Association, recommended the following method of mounting chick embryos whole. The chick is removed and cleaned in the usual manner, and then laid on a glass slide, where it remains permanently. It is then spread out and allowed to dry until the edges become fixed to the slide. It is then treated with a 0·5 per cent. alcoholic solution, until a slight browning occurs. Stain with carmine. The next step is particularly important, as it prevents the further darkening by the reagents, which otherwise injures or ruins the specimen. Four Müller's fluid, one per cent. chromic acid solution, on the slide, and leave it [illegible] The next morning the blastoderm is ready for dehydration in alcohol, and mounting in the usual manner in balsam or [illegible] Embryos prepared in this manner make very beautiful specimens.

THE winter session of the Charterhouse Science [illegible] the United Kingdom) and Art School and Literary [illegible] will, under the presidency of the Rev. Henry [illegible] commence on September 24. During the last session [illegible] students attended this institution; and of this number [illegible] presented themselves for examination, and were successful in obtaining no less than 100 Queen's prizes. At present instruction of a practical character is given in [illegible] Chemical students have the opportunity of working in a well-fitted laboratory capable of holding sixty students. During the session Mr. W. B. Carpenter, F.R.S., will deliver a course of lectures on physiology, to which teachers will be admitted free. This will prove a great boon to the teachers of the metropolis. Dr. Gladstone, F.R.S., Prof. Ferrier, Mr. [illegible] Skertchley, F.G.S., and others will lecture during the session.

THE Berlin Museum is now the fortunate possessor of [illegible] logical treasures which are perfectly unique. The [illegible] expected seal-dures from the Central Aleutian [illegible]

Santa Lucia de Cosumalgapan, Guatemala, purchased for the Museum by Prof. Bastian when upon his American journey.

A SEVERE earthquake was felt three weeks ago in the southern part of the North Island, New Zealand. No lives were lost, but in some of the townships in the Manawater district scarcely a chimney was left standing. In Foxton, for instance, no less than 250 were thrown down. Fissures extending for many miles are reported to have been made, and the railway line was rendered unsafe in that neighbourhood, owing to the undulations of the earth alternately raising and depressing the rails. Since the large shock a good many of a slight nature have occurred. Two shocks of earthquake, each lasting from four to five seconds, were felt at noon on September 2 at Spalato in Dalmatia. The earthquake, which was accompanied by a subterranean rumbling, passed from the south-west to the north-east. It also made itself felt in the neighbouring islands of Brazza and Mascarsa, and in the town of Sebenico. A shock of earthquake was distinctly felt by several individuals at Courtown House, Gorey, Ireland, on August 27, at a quarter to five o'clock. Many heard a rumbling noise as of thunder, some noticed the rattling of doors and windows, and one experienced what he called a "shiver." Lord Courtown noticed a rumbling noise, coming apparently from the north, passing under the house, and so away to the south; the door of the room in which he was sitting rattled. A slight shock of earthquake was felt at Naples at eight o'clock on Saturday morning. At about the same hour severer shocks took place at Popoli, Pescara, and Orsogna, in the Abruzzi. The seismographic instruments on Mount Vesuvius show great activity. In the Abruzzi the earthquake shock has damaged several houses at Chieti and Castelfrentano, where some people have been wounded. At Lanciano two people were killed. At Orsogna one was killed and several were wounded. At Atessa the church of St. Giustina was seriously damaged. There is a great panic everywhere amongst the population. A shock of earthquake occurred at Sanpietro Brazza (Dalmatia) on August 29, at 9 p.m. It lasted four seconds. On September 2, at 10.48 a.m., two strong oscillations were felt at Sign, Spalato, and Brazza (in Dalmatia). Direction east-west. Over forty shocks of earthquake have been felt at Khoi, Persia, between the 28th ult. and September 11. Some houses were destroyed, but no lives have been lost. Most of the inhabitants have left the town, and are encamped outside. The direction of the earthquakes was from north to south. The shocks were accompanied by rumbling noises.

A TERRIBLE disaster has occurred at Elm, a village in the Canton of Glarus. The place has been almost destroyed by a fall of rock. It is believed that at least 200 persons are buried beneath the ruins.

THE German Ornithological Society held its annual meeting early this month at Hamburg. Prof. Landois (Münster) spoke on birds' nests and on the origin of egg-shells; Dr. Reichenow (Berlin) on the classification of ducks.

ACCORDING to the last report of the director of the Central Sanitary Bureau of Japan, the Central Government has granted the necessary funds for the establishment of a hospital in the capital for the special treatment of *kakke*, a disease which has been spreading more and more in the country, and one of the usual symptoms of which is œdema of the legs. It is intended to investigate carefully the causes and proper treatment of the disease at this institution. The average mortality, from all causes, is given at 10·43 in every 1000 of the population, and is stated to be lower than that of places in Europe and America under similar conditions. The director observes, however, that the registration of deaths is not efficiently carried out; but measures are being taken to render this as complete and accurate as possible. It is noticeable that deaths from diseases of the digestive organs and nervous disorders greatly preponderate over all others. In the former the proportion is 24·1 per cent., and in the latter 23·1. Small-pox was the most destructive epidemic of the year, but the number of annual vaccinations is largely increasing. During the year covered by the report it was 1,659,298.

THE second part of Dr. Lang's "Butterflies of Europe" is before us, and quite justifies our mostly commendatory remarks in a recent number. When the work more nearly approaches completion we may probably again find occasion to notice it.

FROM Surgeon-Major Bidie's Report on the Government Central Museum at Madras, we see the number of visitors during 1880–81 was less than in the previous years, due, however, to trivial and temporary causes. The total number of visitors was 173,898, of whom 39·36 were women and girls. Many of course go simply for curiosity, but a very considerable number visit the museum for the express purpose of obtaining information, and there seems no doubt that, under Mr. Bidie's energetic and intelligent management, the institution is doing much good. Very considerable additions have been made during the year, and the whole is in a fair way of being catalogued.

THE additions to the Zoological Society's Gardens during the past week include two Greater Black-backed Gulls (*Larus marinus*), British, presented by Mr. A. Allen; a Blue-shouldered Tanager (*Tanagra cyanoptera*) from South America, presented by Mr. Ernest L. Marshall; a —— Tanager (*Tanagra*, sp. inc.) from Brazil, presented by Dr. Arthur Stradling; a Green Lizard (*Lacerta viridis*), South European, presented by the Misses Parry; two Pantherine Toads (*Bufo pantherinus*) from North Africa, presented by Mr. R. E. Holding; six Common Lizards (*Lacerta vivipara*), two Smooth Snakes (*Coronella lævis*), two Sand Lizards (*Lacerta agilis*), British, presented by Mr. J. T. Mann; a Grey Parrot (*Psittacus erithacus*) from West Africa, four Passerine Parrakeets (*Psittacula passerina*), two Lineated Finches (*Spermophila lineata*) from South America, a Goffin's Cockatoo (*Cacatua goffini*) from Queensland, deposited; six Common Chamæleons (*Chamæleo vulgaris*) from North Africa, purchased. The additions to the Insectarium include larvæ of the Tusseh Silk Moth (*Attacus mylitta*); several larvæ of the Poplar Hawk Moth (*Smerinthus populi*), presented; an imago of the Death's-Head Moth (*Acherontia atropos*), presented by Mr. M. H. Temple, Warwick, and two specimens of *Ceratocampa ixion*, bred from pupæ received a short time since from South America; also many species of aquatic Coleoptera from Askham Bog, near York, presented by Mr. W. A. Forbes, including *Haliplus elevatus*, *Hyphydrus ovatus*, *Hydroporus rufifrons* and *lineatus*, *Colymbetes exoletus* and *grapei*, *Ilybius ater* and *uliginosus*, *Agabus dispar* and *abbreviatus*, *Noterus sparsus*, *Helophorus aquaticus*, *Hydrobius fuscipes*, *Philhydrus melanocephalus*.

OUR ASTRONOMICAL COLUMN

THE DEARBORN OBSERVATORY, CHICAGO.—The annual report from Prof. Hough to the Board of Directors of the Chicago Astronomical Society, dated May last, has been issued. The planet Jupiter has been made a special object of study with the great equatorial, the first observation having been secured on May 6, 1880, and the last on January 30, 1881. The observations made at the Dearborn Observatory do not support the idea that the surface of the planet is "subject to sudden and rapid changes, which may be accomplished in a few days or even a few hours." On the contrary, the observations in question show that all minor changes in the markings or spots have been slow and gradual. "In fact the principal features have been permanent, no material change being detected by micrometer measurement." With regard to the rotation of Jupiter, the discussion of the measures on the great red spot made from September 25, 1879, to January 27, 1881, or over a period of 490 days, gave

Digitized by Google

for the mean value 9h. 55m. 35·2s., but when the individual observations are compared with it, a well-marked maximum displacement of the centre of the spot, to the amount of 1"·4, is exhibited, apparently indicating that it gradually oscillated to this extent in longitude, which on the surface of Jupiter corresponds to about 3200 miles. The observations however may be well represented by making the period of rotation a function of the time; thus the period 9h. 55m. 33·2s. + 0·18s. $\sqrt{t}$ is found to satisfy all the measures with a mean maximum error of 0"·5: the zero-epoch being September 25, 1879, and t the number of days after that date. The mean-rotation period derived from observations of polar spots is 9h. 55m. 35·1s., that deduced from the small spots indicating an average displacement during two months of 2°, or about 4600 miles. The rotation resulting from the observations on equatorial spots is 9h. 50m. 9·8s., with uniform motion. Prof. Hough states that the actual size of the great red spot, as seen with the Chicago telescope (18½ inches aperture) is—length, 29,600 miles; breadth, 8300 miles; and he remarks that smaller telescopes make the approximate length considerably less than the real value.

The nebula near Merope in the Pleiades, of which so much has been written, was not seen with the Chicago refractor in 1879, but as so many observers have described it, Prof. Hough, in conjunction with Mr. S. W. Burnham, made a thorough examination of the locality, with the result that they satisfied themselves that "the nebula did not exist, but that the appearances described by different astronomers was wholly an optical illusion, due to the glow from *Merope* and neighbouring stars." This opinion will probably be disputed in many quarters.

THE WASHBURN OBSERVATORY, WISCONSIN.—No. 1 of "Contributions from the Washburn Observatory, of the University of Wisconsin," has been received. The establishment is under the direction of Prof. Edward S. Holden, late of the Naval Observatory, Washington. Work was commenced in the latter part of April in the present year, with the Clark refractor of 15·56 inches aperture, and Prof. Holden has had the good fortune to secure the co-operation of that eminent observer, Mr. S. W. Burnham, who left Chicago at the beginning of April to accept a post in Washburn Observatory, and although the publication to which we refer is dated May 31, some five weeks after the commencement of operations, thirty-four new double-stars had been detected and measured by Mr. Burnham, and a number of other doubles, discovered in the course of zone-observations in which Prof. Holden took part, were also measured. In addition we have a list of new nebulæ detected in the zone-observations, several of which appear to deserve special attention. On May 2, in R.A. 18h. 8m. N.P.D., 108° 20', a void space was remarked in the Milky Way; it is thus described: "This is a black circular hole (10') in the Milky Way. The stars around it are excessively crowded, and inside there are but two stars, one 10 mag., the other very small."

The number of newly-discovered objects—double stars and nebulæ—of which we have the particulars in this first "Contribution" from the Washburn Observatory, is quite extraordinary, considering the few weeks over which observations have extended. We wish continued success to the Observatory of the University of Wisconsin.

SCHAEBERLE'S COMET.—The following meridian observations S.P. of Comet *c* 1881, made with the transit-circle at the Radcliffe Observatory, Oxford, have been communicated by Mr. E. J. Stone, the Radcliffe observer. The N.P.D. is uncorrected for parallax.

	G.M.T.	R.A.	N.P.D.
	h. m. s.	h. m. s.	° ′ ″
July 31,	9 54 47·5 ...	6 28 21·6 ...	44 3 40·1

(b) 19,	12 35 2·4 ...	10 23 57·4 ...	40 44 50·7

(a) Comet very faint. Only an approximate observation.
(b) Much brighter. Observation good.

ENCKE'S COMET.—The early observations of this body point to a negative correction of the mean anomaly to the extent of 3', which corresponds to a retardation in the time of perihelion passage of about 0d·169. The perturbations from the action of Jupiter during the last revolution have been much greater than between 1875 and 1878, in which latter year the necessary correction to the mean anomaly given by the elements of the late Dr. von Asten, was about one-third as great as in the same direction. The work of his successor, Dr. Backlund, of Pulkowa, has been executed with a most thorough investigation of the planetary perturbations, which is extended to the formation of the ephemeris.

The first glimpse of the comet, so far as we know at present, was obtained by Dr. Hartwig and Prof. Winnecke with the 6-inch comet seeker at the Observatory of Strassburg on August 19. Five days later it was clearly seen in the same instrument as a nebulosity 4' in diameter.

ELONGATIONS OF MIMAS.—The following [illegible] of apparent preceding elongations of the [illegible] upon the same elements as previously used in the [illegible]

GEOGRAPHICAL NOTES

THE International Polar Conference, which was held [illegible] year at Berne, and the previous year at Hamburg, [illegible] month at St. Petersburg. The object of the Conference [illegible] the organisation of a series of stations around the Polar [illegible] for the continuous prosecution of scientific observations [illegible] its last meeting it has lost Lieut. Weyprecht, who was [illegible] originator of the idea of such a scheme. Delegates were present from all the leading European States except England, [illegible] from the United States of America. The first subject [illegible] was the time at which observations should be taken, and [illegible] frequency. Observations will begin for all the expeditions [illegible] the Polar regions, as also for observations in the temperate [illegible] as soon as possible after August 1, 1882, and will [illegible] as possible to September 1, 1883. All the meteorological [illegible] magnetical phenomena will be observed hourly during [illegible] time; and, besides, there will be taken on the 1st and [illegible] each month magnetic observations every five minutes [illegible] twenty-four hours, and every twenty seconds during an hour [illegible] the day fixed on 11 advance, and that everywhere after the [illegible] time of Göttingen. These latter observations have for a special end to obtain a perfect knowledge of perturbations [illegible] magnetic storms, and their connection with the aurora [illegible] On the basis of a programme of observations to be made, [illegible] elaborated by the Hamburg Conference, the obligatory [illegible] logical observations were discussed—*i.e.*, observations which [illegible] the stations must make in order to insure the scientific [illegible] the enterprise. The result of the discussion was the [illegible] the principles, and in part also of the methods and [illegible] of observation, to insure the accuracy and comparability of [illegible] meteorological observations to be made. Happily the Conference [illegible] numbers among its members several distinguished men of [illegible] who have acquired in former expeditions in the Polar [illegible] very great experience of the difficulties to be met with in [illegible] observations, who were able to give advice useful to others [illegible] beforehand those obstacles, by the arrangement of the [illegible] ments, and by the method of taking observations. One [illegible] was devoted by the Conference to visiting the celebrated [illegible] teorological and magnetic observatory of Pawlowsk, and there [illegible] there the choice of the best apparatus. The members [illegible] detail the provisional installations which have been made [illegible] the observatory for inspecting the magnetic instruments [illegible] for the Russian expedition to the mouth of the Lena. At [illegible] third sitting of the Conference, the magnetic observations [illegible] discussed: these also meet with difficulties unknown in [illegible] perate zones. It is not only the great cold, but also the [illegible] nest of the horizontal intensity of terrestrial magnetism, [illegible] the frequency and greatness of the perturbations, which [illegible] observations very difficult and delicate. At the fourth [illegible] the Conference was occupied with observations on the [illegible] borealis, and with the question of facultative observations, [illegible] which are recommended to the expeditions, without being [illegible] sidered indispensable—as observations on the temperature [illegible] soil, evaporation, terrestrial galvanic currents, [illegible] tricity, &c. The conference, among other things, decided [illegible] apply to different institutes to assure their co-operation, and [illegible] request magnetic observatories in the temperate zones, especially [illegible] those in the southern hemisphere, to participate in the [illegible] taneous observations, as also to ask the directors of the [illegible] graphs of different countries to study more accurately [illegible]

Digitized by Google

galvanic currents in the telegraphic wires when aurora borealis or magnetic perturbations appear. Finally the assembly unanimously approved three proposals by Count Wilczek:—1. To found, if possible, a special publication to convey more quickly to the knowledge of the scientific world, as well as to the leaders of the expeditions, the proposals and reports concerning the expeditions, as also their first results. 2. To leave, if possible, on the spot the buildings and other arrangements likely to be useful to future expeditions of the same kind, and to recommend them in each country to the care of navigators or of the inhabitants. 3. To ask railway and steamboat companies to grant a reduction in the fares for the staff and effects of the various international Polar expeditions. The stations proposed, we may state, are two on the north coast of Siberia, one in Novaya Zemlya, one in Spitzbergen, one on Jan Mayen Island, one on the west coast of Greenland, one at Lady Franklin Bay, one in the Behring's Strait region, and the participating countries are Russia, Sweden, Denmark, Germany, Austria, and the United States.

ON the 3rd of next month the members of the Italian scientific expedition for the exploration of the Arctic Seas will embark at Genoa in one of Lovarello's steamers. The zoology will be under the care of Dr. Vinciguerra; the botany will be confided to Dr. Lorenzo, at present residing at Buenos Ayres; mineralogy and geology to Prof. Lovisato, of the University of Sassari; and to Lieut. Roneagli the artistic department is given, for which purpose he will take photographic apparatus, &c. At Buenos Ayres the Commission will embark on a vessel belonging to the Argentine Republic. Lieut. Bove, who will take the command of the expedition, has already left for Buenos Ayres.

THE U.S. Government have been officially advised of the arrival of Lieut. Greeley's Polar Expedition at Lady Franklin Bay, six days after leaving Upernivik. The expedition entered Discovery Harbour on August 11, where a station was formed. The party were all well and plentifully provided.

ADVICES from Copenhagen state that the news received from the Dutch Polar Expedition on board the schooner *Willem Barents* is very unfavourable. Owing to the continuous ice barrier, which extends nearly to Norway, Spitzbergen could not be reached, nor yet even the Bear Islands; and after one more attempt to force through northward, the expedition will return home, as the captain is convinced that this year Novaya Zemlya is completely inclosed in a barrier of ice.

THE Russian Geographical Society has prepared short notices on the progress of different branches of geographical science from 1875 to 1881, *i.e.* from the second to the third Geographical Congress. Three of them are printed: (1) "Aperçu des Travaux Hydrographiques"; (2) M. Bogdanow: "Aperçu des Recherches Zoo-géographiques en Russie"; (3) P. Matveiew and A. Stichinsky: "Aperçu des Études sur le Droit coutumier en Russie." Besides there are in preparation notices on botanical geography by M. Bataline, on geology by M. Alénitzin, and on Count Uvarow's work on the Stone Age in Russia, by L. Maikof. A. W. Grigorief and Dr. A. Woeikof will be the Russian official delegates to the third Geographical Congress. The absence of the celebrated Russian cartographers is much to be regretted; one of them, General Stubendorff, hoped to attend the Congress, but now it is known he will not be present.

THE new number of the Geographical Society's *Proceedings* is remarkable for the excellent map of Khorasan and the neighbouring countries, in illustration of Col. Stewart's account of his journey and investigations in the Tekke Turkoman country and the region of the Tejend and Murghab Rivers. The map goes beyond Merv and Herat on the east and takes in the south-east part of the Caspian on the west. There is also an article on the recent journey of two Baptist missionaries from Vivi, by the north bank of the Congo, to Stanley Pool. Dr. Matteucci's great geographical achievement in North Central Africa and subsequent death in London are sympathetically referred to in the Geographical Notes. The Society's telegram of condolence to the Geographical Society at Rome appears to have been much appreciated there, as it has been reproduced in the Italian papers. One of the most interesting items in the present number is a letter from Mr. W. H. Dall, of the United States Coast Survey, on "The Chukches and their Neighbours in the North-Eastern Extremity of Siberia." The letter is written in reply to some strictures which Lieut. Nordqvist, of the *Vega*, addressed to the St. Petersburg Geographical Society, and which were noticed in the *Proceedings* for June.

THE Berlin African Society has received further news from several German explorers in Western Africa. Dr. Pogge and Lieut. Wissmann were at Malange at the end of May, hoping to start early in June, and to reach Kimbundo at the end of that month. From Robert Flegel news are to hand up to June 4. The members of the station at Kokoma are occupied with scientific collections and the exploration of the environs. Dr. Stecker is trying to reach the Central African lakes from Abyssinia.

A NEW volume of travels by Mr. E. A. Floyer, F.R.G.S., &c., entitled "Unexplored Balûchistan, a Survey of a Route through Western Balûchistan, Mekran, Bashakird, Persia, Kurdistan, and Turkey," will be published during the autumn by Messrs. Griffith and Farran. Mr. Floyer was the first to explore the wild district of Bashakird; he contributed a paper on that little-known country to the Plymouth meeting of the British Association. Besides the narrative, which is full of interesting personal incident and adventure, the work will contain original illustrations, a map, vocabularies of dialects, lists of plants collected and tabulated, and observations, astronomical and meteorological.

PROF. SIMONY has published a list of the greatest depths of various Alpine lakes, which may interest our readers: Gmunden Lake, 191, Hallstadt Lake 125, Attersee 171, Mondsee 67, Wolfgang Lake 114, Achensee 132, Königssee 188, Lake of Constance 276, Chiemsee 89, Starnberg Lake 131, Lake Leman 309, Neufchâtel Lake 144 metres. The last-named four measures 92, 57, 589, and 240 square kilometres surface. The greatest depth of the northern part of the Adriatic is only 243 metres.

SCIENTIFIC SERIALS

The Journal of the Royal Microscopical Society, August, 1881, contains:—On some remarkable enlargements of the axial canals of sponge spicules and their causes, by Prof. P. Martin Duncan (plates 7 and 8).—On a blue and scarlet double stain, suitable for nerve and other animal tissues, by Dr. B. Wells Richardson. With the summary of recent researches, zoology, and botany, pp. 575 to 651; Microscopy, pp. 651-711.—Proceedings of the Society for June.

The American Naturalist for August, 1881, contains: The great crested fly-catcher, by Mrs. Mary Treat.—On the reasoning faculty of animals, by Joseph F. James.—On the progress of anthropology in America during 1880, by O. T. Mason.—On the manuscript Troana, by Cyrus Thomas.—The Editor's Table.—Some recent literature.—General notes and scientific news.

Proceedings of the Academy of Natural Sciences of Philadelphia, Part 1, January to May, 1881, contains: Dr. Jos. Leidy, Rhizopods as food for young fishes.—Thomas Meehan, note on treeless prairies; motility in plants; sexual characters in *Fritillaria atropupurea*, Nutt.—R. Arango, descriptions of new species of terrestrial mollusca of Cuba.—Rev. H. C. McCook, on the honey-ants of the Garden of the Gods. (This detailed memoir on the structure and habits of *Myrmecocystes melliger* is illustrated with ten plates.)—John A. Ryder, on the structure, affinities, and species of Scolopendrella. *S. gratiæ* is figured and described. An American specimen of what is presumed to be *S. notacantha* is also figured. The author places these strange insects in an order Symphyla, indicating that it has affinities to Thysanura; trachea are present. Henry Hemphell, on the variations of *Acmæa pelta*.—R. E. C. Stearns, observations on Planorbis (with many woodcuts).

American Journal of Science, August.—Method of obtaining and measuring very high vacua with a modified form of Sprengel pump, by O. N. Rood.—Geological relations of the limestone belts of Westchester county, New York; origin of the rocks of the Cortlandt series, by J. D. Dana.—New meteoric iron of unknown locality, in the Smithsonian Museum, by C. U. Shepard.—The relative motion of the earth and the luminiferous ether, by A. A. Michelson.—Observations on the light of telescopes used as night-glasses, by E. S. Holden.—Nature of dictyophyton, by C. P. Whitfield.—Observations on the comet, by H. Draper, C. A. Young, W. Harkness, L. Boss, and A. W. Wright.

Fættinger.—Study on the hypophysis of Ascidians and the neighbouring organs (second paper), by M. Julin.—Note on the fossiliferous Porphyroids met with in Brabant, by M. Potsain.

Reale Istituto Lombardo di Scienze e Lettere. Rendiconti, Vol. xiv, fasc. xii, xiii.—Researches on the phenomena of sense, motion, circulation, and respiration in hypnotism, and on their modification by æsthesiogenic agents, by Prof. Tamburini and Dr. Seglli.—On some products of tran-formation of chinoline, by Prof. Körner.—Theorem on linear systems in projective measurements, by Prof. D'Ovidio.—Consequences of pachymeningitis and hematoma of cerebral membranes, by Prof. Sangalli.—Fasc. xiv.—On the small volcano of Querzola in the province of Reggio, by S. Taramelli.—On the resistance to passages of the voltaic current in an iron wire at different temperatures, by Dr. Paloni.

Rivista Scientifico-Industriale, July 1 and 15.—Determination of vapour density, by Dr. Valente.—Palæontological peregrinations in the Pliocene of Mount Falcone Apennine, in the province of Fermo (Marche), by Prof. Spada.—On determination of the electromotive force of the Voltaic couple by Fuchs' method, by Dr. Guglielmo.

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, September 5.—M. Wurtz in the chair.—The following papers were read:—The direct-vision spectroscope applied to physical astronomy, by M. Zenger. One may (as before shown) compound refringent media who e index for the red ray A is less than that of crown glass or quartz, while the index for the violet ray H is much greater. The spectrum so produced is fan-shaped, and, with a single dispersion parallelepiped (two similar prisms with their refringent angles opp site), may be made of considerable length (25° and more). With o e arrangement all the rays, except blue or red, may be eliminated, and the sun, e.g., viewed in monochromatic light. M. Zenger specifies various combinations of quartz or brown glass with anesh d, benzene, alcohol, &c. He obtains effects equal to those of the most powerful spectroscopes hitherto made.—Influence of nutrition on poisoning with strychnine, by M. Delaunay. Strychnine affects more quickly and intensely strong frogs than weak ones; frogs well fed than those which have been fasting; frogs that have been [illegible] than those at rest; frogs that are [illegible] after injection than those which are [illegible] by the leg than one hung by the [illegible] than one which has been bled; the [illegible] than the left, &c.—Observations of Co[illegible] at Marseilles Observatory, with an equat[illegible] ture, by MM. Borelly and Coggia.—Ghe[illegible] belle's comet (e 1881) in the same way and place [illegible] —Observations of Knobel's comet, by M. Tempel [illegible] it on the 21st ult. A letter from M. Lewy [illegible] Struve found it on the 23th (MM. Winnecke and [illegible] Strasburg about the same time). The comet [illegible] Tempel) was large, but very diffuse, without [illegible] sation towards the centre, and so, very difficult [illegible] the light of comets, by M. Rayet. He cannot [illegible] not yet in a position to say that comets have a [illegible] own, due to incandescence of cometary matter [illegible] tinuity of the spectrum, and the bright lines and [illegible] arise from reflected light as affected in traversing [illegible] vapours of the comet; the same cause as affects [illegible] the sun when near the horizon. Only the phenomena [illegible] aggerated in comets by reason of the enormous [illegible] absorbent layers, their rich ess of chemical compounds [illegible] weakness of the light they reflect to us.—On the [illegible] meteors from July 25 to 30, 1881, by M. Chapelas [illegible] Fumalhaut. The hourly average increased rapidly [illegible] evening and morning hours, and there was a second [illegible] de-cence shortly before sunrise. It would then [illegible] stream of meteors moves in opposite direction to [illegible] This is corroborated by the fact that the morning [illegible] cially after 5 a.m., all moved with great velocity, and [illegible] brilliant. They were all sensibly displaced to the [illegible] ecliptic; their direction is probably very little [illegible] plane.—On ferruginous carbonated waters. By [illegible] Neutral alkaline carbonates precipitate such waters [illegible] neutral alkaline earthy carbonates also have [illegible] more slowly. Alkaline and alkaline-earthy [illegible] after ferruginous water. Chlorides and [illegible] retard the decomposition of ferruginous waters [illegible] disturbing influence of neutral alkaline carbonates [illegible] the relation between the richness of ferruginous [illegible] waters and the presence of these saline compounds [illegible] of neutral carbonate of calcium explains the [illegible] siderable beds of limonite in calcareous strata.—[illegible] ly the vesical mucus, by MM. Carnevale and [illegible] sound bladder absorbs the normal elements of [illegible] toxical or medicamentary substances (e.g., sulphate [illegible] nine) are not absorbed.—On experimental tuberculosis [illegible] Brunet.

ANNOUNCEMENT.

THE INTERNATIONAL ENCYCLOPÆDIA OF SURGERY.

A SYSTEMATIC TREATISE ON THE THEORY AND PRACTICE OF SURGERY

By Authors of Various Nations.

EDITED BY JOHN ASHHURST, JR., M.D.,

Professor of Clinical Surgery in the University of Pennsylvania.

In Six Volumes, Royal Octavo. Illustrated with Chromo-lithographs and Wood Engravings.

THE PRICE OF EACH VOLUME WILL BE **31s. 6d.** *BOUND IN CLOTH, AND THE FIRST VOLUME IS EXPECTED TO BE READY* **IN OCTOBER, 1881** *THE SUBSEQUENT VOLUMES WILL BE PUBLISHED AS NEARLY AS POSSIBLE AT REGULAR INTERVALS OF THREE MONTHS.*

CONTENTS OF THE VOLUMES.

Vol. I.—General Surgery. Operative, Minor, and Plastic Surgery. Amputations.
Vol. II.—Injuries and Diseases which may occur in any Part of the Body. Venereal Diseases, Injuries and Diseases of various Tissues of the Body.
Vol. III.—Injuries and Diseases of the Nerves, Blood-Vessels, and Bones.
Vol. IV.—Injuries and Diseases of the Joints. Excisions and Resections. Treatment of Deformities. Injuries and Diseases of various Regions of the Body.
Vol. V.—Regional Surgery Continued.
Vol. VI.—Regional Surgery Concluded. History of Surgery. Appendix. General Index to the whole Six Volumes.

Among other distinguished men the following are contributors to the work:—

Messrs. MACMILLAN & CO.'S PUBLICATIONS

ANTHROPOLOGY: an Introduction to the Study of Man and Civilisation. By E. B. TYLOR, D.C.L., F.R.S. With Illustrations. Crown 8vo. 7s. 6d.

Extract from Professor Flower's Address on Biology at the British Association.

"Within the last few months the study of our subject in this country has received an impulse from the publication of a small—small in size, it is true, but full of materials for thought and information—the 'Anthropology' of Mr. E. B. Tylor, the first work published in English with that title, and one very different in its scope and method from the old ethnological classics.

"The immense array of facts brought together in a small compass, the terseness and elegance of the style, the philosophical feeling with which difficult and often burning questions are treated, should give this book a wide circulation among all classes, and thoroughly familiarise both the word and the subject to English readers."

FRENCH HISTORY FOR ENGLISH CHILDREN. By SARAH BROOK. With Coloured Maps. Crown 8vo. 6s.

"Miss Brook has succeeded admirably. . . . Her book is lucidity itself; she has neglected, so far as we can judge, nothing that was worth noting . . . though she writes invariably with praiseworthy self-restraint, she has made her subject as attractive as well as instructive . . . more advanced students may read the book with pleasure, and even find it useful for purposes of general reference."—*The Times.*

NATURE SERIES. NEW VOLUME.

FASHION IN DEFORMITY, as Illustrated in the Customs of Barbarous and Civilised Races. By W. H. FLOWER, LL.D., F.R.S., &c. With [illegible] Crown 8vo. 2s. 6d.

"Professor Flower's volume is as interesting as it is instructive."—*St. James's Gazette.*

NEW TESTAMENT IN THE ORIGINAL GREEK. The Text Revised by B. F. WESTCOTT, D.D., Regius Professor of Divinity, Canon of Peterborough, and F. J. A. HORT, D.D., Hulsean Professor of Divinity, Fellow of Emmanuel College, Cambridge: late Fellows of Trinity College, Cambridge. 2 vols. crown 8vo. 10s. 6d. each.

VOL. I. TEXT. VOL. II. INTRODUCTION AND APPENDIX.

FIRST LESSONS IN PRACTICAL BOTANY. By G. T. BETTANY, M.A., F.L.S., Lecturer in Botany at Guy's Hospital Medical School. 18mo. 1s.

"This is an excellent little book. Its diligent study by teachers as well as pupils would give descriptive botany the educational value which is so often claimed for it."—*Nature.*

NOTES AND THOUGHTS ON GARDENS AND WOODLANDS. By the late FRANCES J. HOPE. Edited by ANNE J. HOPE JOHNSTONE. Crown 8vo. 5s.

A NEW FIRST LESSON BOOK ON AGRICULTURE, FOR SCHOOLS.

AGRICULTURE, THE ALPHABET OF. THE PRINCIPLES OF. By Professor HENRY TANNER, M.R.A.C., F.C.S., Examiner in the Principles of Agriculture to the Government Department of Science. Extra fcap. 8vo. 6d.

MACMILLAN'S ELEMENTARY CLASSICS.—NEW VOLUME.

PLATO — EUTHYPHRO AND MENEXENUS. Edited by C. E. GRAVES, M.A. 18mo. 1s. 6d.

By SIR JOHN LUBBOCK, Bart., M.P., F.R.S., D.C.L.

THE ORIGIN AND METAMORPHOSES OF INSECTS. With numerous Illustrations. Second Edition. Crown 8vo. 3s. 6d. (NATURE Series.)

ON BRITISH WILD FLOWERS CONSIDERED IN THEIR RELATION TO INSECTS. With numerous Illustrations. Second Edition. Crown 8vo. 4s. 6d. (NATURE Series.)

SCIENTIFIC LECTURES. With Illustrations. 8vo. 8s. 6d.

POLITICAL AND EDUCATIONAL ADDRESSES. 8vo. 8s. 6d.

MICROSCOPES.

Unequalled by any other Maker at the same Price. Intending Purchasers should apply to the Manufacturer,

EDMUND WHEELER,

480, Tollington Road, Holloway, N., London.

OWENS COLLEGE, MANCHESTER.

TECHNOLOGICAL CHEMISTRY COURSE.

A Detailed Syllabus of the Complete Course in Technological Chemistry will be forwarded on application.

The next Session commences on October 4th.

J. HOLME NICHOLSON, Registrar.

UNIVERSITY COLLEGE, NOTTINGHAM.

The SESSION commences early in October.

The Prospectus may be obtained on Application to the Secretary.

FIRTH COLLEGE, SHEFFIELD.

The SESSION will COMMENCE on TUESDAY, October 4, at 2 p.m.: when an INTRODUCTORY ADDRESS will be delivered by the PRINCIPAL, and the Certificates gained at the late Annual Examination Distributed by the President of the Council.

Prospectuses may be obtained on application to

ENSOR DEURY, Registrar.

UNIVERSITY COLLEGE, BRISTOL.

The next Session will begin on October 10th, 1881. The College supplies for persons of either sex, above the ordinary school age, the means of continuing their studies in Science, Languages, History, and Literature. The Chemical Laboratory is open daily from Ten to Five. Arrangements have been made by which Students in the Engineering Department can spend the six summer months as Pupils with various Engineering Firms in and near Bristol. Information with regard to the lodging of Students will be given on application. For Prospectus and further information apply to

J. N. LANGLEY, LL.D., Registrar and Secretary.

METALLURGICAL LABORATORY,

KING'S COLLEGE, STRAND, LONDON, under the direction of Prof. A. K. HUNTINGTON.—Methods of Extracting Metals from their Ores: Assaying and Mineral Analysis; Refractory Materials; the Relation between the Mechanical and Chemical Properties of Metals and Alloys studied with the aid of Testing Machinery: Electro-Metallurgy, &c. Laboratory open every day from 1st October, and on Friday Evenings from 14th October. It is optional to attend the Laboratory during any portion of a week.

CIVIL SERVICE COMMISSION.—An

Open Competition in London for one situation as SECOND-CLASS ASSISTANT in the Royal Observatory, Greenwich, October 26. Preliminary Examination in London, October 25 (Age 18-25). For Regulations and Forms of Application, address the SECRETARY, Civil Service Commission, London, S.W.

THE MASON SCIENCE COLLEGE, BIRMINGHAM.

SESSION 1881-82.

I.—DEPARTMENT OF SCIENCE AND ARTS.

The Session will commence on MONDAY, the 3rd of October, 1881. Students under sixteen years of age will be required to pass a Preliminary Examination.

II.—EVENING CLASSES.

These will commence on WEDNESDAY, the 5th October, 1881.

The Calendar of the ensuing Session, containing full information as to the aims and objects of the College and the Courses of Instruction, is now ready, and may be obtained from the publishers, Messrs. CORNISH BROTHERS, Birmingham and Manchester, price 1s.

GEO. H. MORLEY, Secretary.

LIVERPOOL COLLEGE OF CHEMISTRY, DUKE STREET.

LECTURERS—GEO. TATE, Ph.D., F.C.S., and GRANVILLE H. SHARPE, F.C.S.

The Day Lectures and Practical Courses commence on OCTOBER 7th; the Evening Courses on OCTOBER 3rd.

Prospectuses will be forwarded on application.

BIRKBECK INSTITUTION.

EXPERIMENTAL PHYSICS.

Mr W. J. WILSON, F.C.S., M.S.T.E., will commence a Course of about SIXTY Experimental Lectures on Electricity, Magnetism, Sound, Light and Heat, on FRIDAY, October 7th, at 8 p.m.; to be continued on succeeding Fridays at the same hour; terminating with the Government Examinations in May. Fee for the Course, £2.

For detailed syllabus, &c., apply to the LIBRARIAN.

A COURSE OF LECTURES on ANIMAL

MORPHOLOGY, comprising the Anatomy and Physiology of Typical Animals illustrating each class of the Animal Kingdom, will be delivered by Mr THOMAS DUNMAN at the Birkbeck Institution, Southampton Buildings, Chancery Lane, on THURSDAY Evenings at 7 o'clock, commencing October 6. Fees per Session: Members of the Institution, 15s.; non-Members, 1l. Prospectus Gratis on application.

LIVING SPECIMENS FOR THE MICROSCOPE.

THOMAS BOLTON, NATURALIST and MICROSCOPIST,

STUDIO, 57, NEWHALL STREET, BIRMINGHAM.

T. B. has last week sent to his subscribers the Commencement Series of *Limnæa Stagnalis*, which was discovered by a Member of Mr. Bolton's Class, Mr. Sowerby, in the Botanical Gardens, Regent's Park. Mr. Sowerby is enabled to distribute these through the courtesy of Mr. Thiselton-Dyer, of the Royal Gardens, Kew, with permission from Sir Joseph Hooker.

Weekly announcements will be made in this Journal of specimens T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in course of Six Months for Subscription of £1.

Prize List of Specimens on application, with stamped addressed envelope.

Portfolio of Drawings, Six Parts, 10s. each.

BEDFORD COLLEGE (FOR LADIES)

8 AND 9, YORK PLACE, PORTMAN SQUARE, LONDON.

The SESSION will begin on THURSDAY, October 13th.

A Course of Lectures on Logic will be given by W. C. Coupland, B.A., and a Course of Lectures on Geology by Prof. T. G. Bonney, M.A., F.R.S., F.G.S.

Prospectuses, with full particulars of Scholarships, Exhibitions, &c., may be had at the College.

F. KENSINGTON, Hon. Sec.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

ALBERT EMBANKMENT, LONDON, S.E.

The WINTER SESSION of 1881-2 will commence on October 1st with an Introductory Address will be delivered by Dr. Barnes, F.R.C.P., F.R.C.S., &c., at 3 p.m.

Two Entrance Science Scholarships, of £100 and £50 respectively, open to all new Year's Students, will be offered for competition. The Scholarships will be held on the 5th, 6th, and 7th of October, and the Subjects will be Chemistry and Physics, with either Botany or Zoology at the option of Candidates.

Special Classes are held throughout the year for the "Matriculation," "Preliminary Scientific," and "First M.B." Examinations of the University of London.

All Hospital Appointments are open to Students without fees. Numerous Scholarships and Money Prizes of considerable value are awarded in the Sessional Examinations, as also several Silver and Gold Medals.

The Fees may be paid in one sum or by instalments. Special Arrangements can be made for Students entering on their Second or subsequent years, and for Dental Students and for Qualified Practitioners.

Several Medical Practitioners and Private Families residing in the neighbourhood receive Students for residence and supervision, and a list of these Inspected and Approved Lodgings is kept in the Secretary's Office.

Prospectuses and all particulars may be obtained from the Secretary, or from Dr. GILLESPIE.

W. M. OGLE, M.D., Dean.

ST. THOMAS'S HOSPITAL, ALBERT EMBANKMENT.

UNIVERSITY OF LONDON MATRICULATION AND PRELIMINARY SCIENTIFIC EXAMINATIONS.

The Special Classes in the Subjects for the above Examinations will be commenced at St. Thomas's Hospital Medical School on Monday, 10th October, and Tuesday, 11th October, respectively.

The Preliminary Scientific Instruction Forms the best preparation for the Entrance Science Scholarships, value £100 and £50, awarded annually in October.

Prospectus and all particulars from the Secretary, Dr. GILLESPIE.

W. M. OGLE, M.D., Dean.

THE MIDDLESEX HOSPITAL.

The WINTER SESSION will open on MONDAY, October 3rd, with an Introductory Address by Dr. R. Douglas Powell.

The Medical School, which has lately been considerably enlarged, provides the most complete means for the education of Students proposing to join the University of London, the Colleges of Physicians and Surgeons, or other Licensing Bodies.

Two Entrance Scholarships, of the annual value of £50 and £30 respectively, tenable for two years, and a Science Scholarship, value £20, will be competed for on September 30th and October 1st.

Further information may be obtained from the Dean or the Resident Medical Officer at the Hospital.

ANDREW CLARK, M.P.

BRYCE-WRIGHT'S LATEST ARRIVALS.

GEMS.—Unique Cat's Eye, weight nearly 40 carats. Very fine Sapphire, 95*l*. Matchless Opal, weighing 34*l* carats, one of the finest known. Alexandrites, Hiddenites, etc., and extraordinary Star-Sapphire, weighing 250 carats.

MINERALS.—Hiddenites, Spheres, Canada; green Tourmalines, Castor, Pollux, from Elba, Ireland, and Precious Opals from Australia.

METEORITES from following Localities:—Wold Cottage, Yorkshire, Bois de la Fontaine, Loiret, Soko Banja, Indian.

ANTHROPOLOGY: an Introduction to the Study of Man and Civilisation. By E. B. TYLOR, D.C.L., F.R.S. With Illustrations. Crown 8vo. 7*s.* 6*d.*

Extract from Professor Flower's Address on Biology at the British Association.

"Within the last few months the study of our subject in this country has received an impulse from the publication of a book—small in size, it is true, but full of materials for thought and instruction—the 'Anthropology' of Mr. E. B. Tylor, the first work published in English with that title, and one very different in its scope and method from the old ethnological treatises.

"The immense array of facts brought together in a small compass, the terseness and elegance of the style, the good taste and feeling with which difficult and often burning questions are treated, should give this book a wide circulation among all classes, and thoroughly familiarise both the word and the subject to English readers."

FRENCH HISTORY FOR ENGLISH CHILDREN.

By SARAH BROOK. With Coloured Maps. Crown 8vo. 6*s.*

"Miss Brook has succeeded admirably. . . . Her book is lucidity itself; she has neglected, so far as we can judge, nothing that was worth noting . . . though she writes invariably with praiseworthy self-restraint, she has made her concise story attractive as well as instructive . . . more advanced students may read the book with pleasure, and even find it useful for purposes of general reference."—*The Times.*

EGYPTIAN EXCAVATIONS AND MUMMIES

THE recent excavations in Egypt have been productive of great results to archæology and the history of Egypt. One site, which has yielded unexpected additions to the early period of the country, has been excavated on scientific principles under the direction of M. Maspero, the present superintendent or director of the Archæological Department. It is his intention to open the whole group of unexplored pyramids, in order to find the sequence of monarchs of whom they were the sepulchres, and to discover any inscriptions with which they may have been decorated. An examination of the whole group of pyramids indeed was formerly made by J. Shay Perring, C.E., at the expense of Col. Howard Vyse, who spent a fortune in pyramidal researches; but the excavations of Perring were chiefly devoted to the examination of three great pyramids of Gizeh, those of Cheops, Chephren, and Mycerinus, and although he examined the whole group in the scientific manner of an engineer, by some fatality he appears not to have penetrated into the interior of the smaller ones, which are now in process of examination by M. Maspero. The conviction which that *savant* has arrived at is that these pyramids are arranged in symmetrical groups, each group holding the remains of the monarchs who followed each other in chronological succession. The group just discovered consists of three pyramids at Sakkara, of small dimensions, lying to the N. and E. of the step-shaped pyramid, and on the road to the Serapeum, the sepulchres of three monarchs of the sixth dynasty, Ra-meri or Mira, whose name was Pepi or Phiops, a king who is said to have reigned 100 years all but an hour; his successor, Merienra, named Har-em-saf, or Ta-em-saf, and a king called Una. They seem all to have been constructed on the same principle, having inclined entrances leading to sepulchral chambers with pointed roofs, the walls of the passages and chambers covered with hieroglyphs coloured green, the ceilings of the sepulchral chambers with pointed roofs on which were stars in white upon a black ground, indicative of the hours of the night. The inscriptions of these chambers are of interest purely mythological, no historical fact or allusion being mentioned in them, but their contents consisting of prayers similar to those in the Book of the Dead, or Ritual, and chiefly referring to the myth of Osiris and Hades, especially the identification of the kings with Osiris as the son of Nut and Seb, and his following the course of the constellation Orion, rising and setting with that constellation, allied with the star *Sebt*, or Sothis, and the progress of the king to the *Aahlu* or Egyptian Elysium, and in the account of the Island of the Fields of Ho-tep, or Peace, recalling to mind Eden, mention is made of a tree of life. In the Pyramid of Pepi, the Phiops of the sixth dynasty, who is said by the history of Manetho to have reigned 100 years all but an hour, and who must consequently have ascended the throne quite a boy, was found the remains of a sarcophagus of black and white granite of unfinished work, which had been broken, and another in the south-east corner of the chamber of the same material, which had been let into the masonry. In the vicinity of this sarcophagus on the west side between this and the wall was found amidst a heap of rubbish remains of dresses and mummy bandages varying from yellow to dark brown of extreme fineness; of the mummy itself an embalmed hand in good condition was only found, and even this may be considered remarkable, as the bodies of the earlier period were only dried, and not embalmed, and generally fall to pieces when exposed to air. The pyramid was indeed small, considering the long reign of Pepi. The Pyramid of Merienra, or Har-em-saf, which resembled in general character that of Pepi or Phiops, had two sarcophagi of red granite close to one another, the cover of one removed and hidden under blocks of stone. The other held a body mummied, which was that of the king; it had been anciently plundered of its ornaments, but embalmed with the greatest care, the skin well preserved, the traits of the countenance distinct, the eyes closed, the end of the nose fallen in, the stature of medium height, and the limbs youthful. This king was the successor of Phiops. The third pyramid of the group was of Noferkara or Nephercheres, but no details of the inscriptions have as yet been published, although they probably refer to the Osiris myth, like the others. The details of the size of coffins and mummies of this pyramid are still wanting. Each pyramid had a special name: that of Pepi was called Mennefer, that of Ha-rem-saf was Shanefer, that of Noferkara also Mennefer. Compared with the great Pyramids of Gizeh, they are far inferior, but the inscriptions in them offer an interest greater than that of the plain Gizeh Pyramids. The only question is whether the mummies found in them are contemporaneous with the sixth dynasty, which appears most probable, or subsequent usurpations, of which there is no monumental or inscribed evidence.

The next remarkable discovery is that of the thirty-nine mummies, several of kings, in a subterraneous well or pit not very far from the edifice of the Deir-el-Bahari. This remarkable structure, consisting of a temple on a platform with chambers let into the solid rock, had been published by Marriette Pasha, and had been suspected by Brugsch Bey to be the site of the sepulchres of the early monarchs of the eighteenth dynasty. The temple itself had been commenced by the queen Hatasu or Hasheps, daughter of Thothmes I. and wife of Thothmes II., and its sculptures commemorated the expedition made by that queen to Punt or Somali, the treasures brought from thence in gold, silver, frankincense, besides trees of that material, besides giraffes, cynocephali, large dogs. Besides which they give representations of the inhabitants and of the Egyptian fleet which descended the Red Sea on the voyage of amity or discovery promoted by the Egyptian queen.

In the well or pit of the Deir-el-Bahari, which was formed of bricks of conical shape stamped with inscriptions, on which could be traced the titles of the high priest of Amen-ra thus used by the monarchs of the twenty-first dynasty, were found the coffins, mummies, and other objects which appear to have been there deposited in the reign of Herhor, first monarch of the twenty-first dynasty, and of another king, Panetem or Pinotem, of the same dynasty. The cause of the removal of the mummies deposited in the Theban sepulchres, such as the El Assasif and the Biban-el-Molook, is stated on some of the wraps of the mummies to have been the apprehension

Digitized by Google

of a foreign invasion, and that possibly of the Assyrians, whose arms had made great progress in Central Asia. According to Brugsch Bey the twenty-second dynasty was Assyrian, and he identifies the name of the monarch with that race; but at all events they were never Assyrian monarchs, such names as Shashanq or Shishak, Namrutha or Nimrod, not having been found in the Assyrian annals, although Uasarkan or Sargon, and Takelloth or Diglath may correspond with Assyrian kings.

From the El Assasif had been removed the mummy of Taakan, also known as Skanenra, which was formerly deposited at the Drah Abu-el-Neggah with its three inscribed coffins, and which was intact at the time of Rameses IX. about B.C. 1150. It was in his reign that the quarrel of the Egyptian kings with the Shepherd Kings commenced, and he is mentioned in the celebrated Sallier Papyrus. The mummy of Aahmes or Amosis I. in three plain cases was also found amongst the coffins, but it is not known where this king was buried; as he succeeded Skanenra, his tomb was probably somewhere in the vicinity. The mummy of Aahmes Nefertari was also found, it is said, in three cartonages with paintings on a white ground. Another queen, Aahhotep, daughter of the King Aahmes, was also found, and it will be recollected that this was the name of the queen whose mummy and coffins, and gold and silver jewellery, and arms were discovered by fellaheen at the Biban-el-Moluok, a few feet below the surface. She was wife of Kames and mother of Aahmes, while the queen of the Deir-el-Bahari was the wife of Amenophis I. The mummy of Amenhotep I. or Amenophis was found in a wonderful state of preservation, painted and varnished, and with wreaths of flowers so exquisitely preserved that they retain all their colour like recent flowers kept and pressed between the leaves of books. These flowers, it will be remembered, are above 3000 years old, and their preservation is probably due to their having been buried in hot sand, a mode still in use in Palestine, by which means botanical specimens retain their colour for a long time unchanged, a process perhaps known to the ancient Egyptians, although wreaths and flowers, even of the Roman times, from Egypt are brown and semicarbonised. The tomb of Amenophis I. is mentioned as at the Drah Abu-el-Neggah in the Abbot Papyrus, and the body transported thence of Thothmes I., his son; the mummy case, considerably mutilated, was only found, and this had been appropriated by Pinotem. The mummy of Thothmes II., in three mummy cases, was likewise discovered. That of Thothmes III., the great and warlike monarch of the eighteenth dynasty, was found in a single coffin much mutilated, his body broken into three pieces and rifled in ancient times, but with an inscribed ritualistic linen roll said to prove the identity of the mummy. Of the other personages of the eighteenth dynasty were the mummies and coffins of the Prince Saamen, the Princess Satamen, a princess and king's sister, but unmarried, named Hanta-em-hu; and a similar royal sister and queen named Me-han-ta-emhu, child of Hanta-ena-hu, had been removed at the time of the twenty-first dynasty; another unmarried queen-sister named Miramen, and Nebseni, a priest or flamen of a Pharaoh. All these coffins of the eighteenth dynasty have a certain similarity with each other. Those of the nineteenth are Rameses I., whose tomb and sarcophagus are at the Biban-el-Moluok. There is some uncertainty in the different accounts which have come to hand whether there are three coffins or one, and if the mummy was deposited at the Deir-el-Bahari. The mummy of Seti I., whose tomb is in the Biban-el-Moluok, in alabaster sarcophagus in the Soane Museum of London, is well preserved in one wooden coffin; the mummy of one of the Ramessids, apparently the twelfth, not the queen, is reported, in a plain coffin, the features not unlike in the shroud, covered with lotus flowers, looking remarkably fresh; this also came from the Biban-el-Moluok. These mummies, it is stated, were removed under apprehension of a foreign invasion. Then follow the coffins and mummies of the twenty-first dynasty. The queen Notem, mother or wife of Herhor, of whom there is a papyrus in the British Museum, exhibited by H.R.H. the Prince of Wales, in a badly-preserved but intact coffin. Panotem or Pinotem, high-priest of Amen, in three coffins of the style called *richi* by Marriette, and gilded face. He was, besides high-priest, a *saten sa Kash*, Prince of Cush or Æthiopia, according to the inscription in Lepsius' *Königsbuch*; the queen, Ramaka or Makara, who assumed the same prenominal title as Hatasu of the eighteenth dynasty, who is in three coffins with the youthful queen, called the "lady of the two countries" or absolute queen-heiress, embalmed in a sitting posture, either having died in a fit or at her birth, and named Mutemhat; the king, Pinotem II., hastily deposited in the coffins of Thothnes I., the mummy has been partially unwrapped and the features exposed, which have a singular resemblance to those of Voltaire, with a similar satiric smile or grin, a peculiarity also found on a female papyrus ritual in the British Museum, probably of the same period; the queen-mother, Hantaa, whose coffin had found its way to the Boolak Museum prior to its discovery; in three cases, the prince Masaharta son of Pinotem II. in the same; the queen Aasekhebt or Hesemkheb, in as many cases, who appears to have been the wife of Menkheperra; another princess called Nesikhonsu; Tet-ptahaufankha in an appropriate coffin, and four other priests and functionaries. Several other objects were found in the pit: a leather tent embroidered with names, boxes with royal names, boards with inscriptions, and five rituals of the monarchs of the *later* dynasty, but the whole of the details—amulets, inscriptions, and style of art—cannot be known until the mummies are unrolled and all peculiarities carefully examined, for the remarkable find will afford invaluable data for Egyptian archæology, especially the sepulchral division.

TWO SPIDER BOOKS

The Spiders of Dorset, with an Appendix containing Descriptions of those British Species not yet found in Dorsetshire. By the Rev. Octavius Pickard-Cambridge, M.A., C.M.Z.S., &c. From the *Proceedings* of the Dorset Natural History and Antiquarian Field Club, edited by Prof. James Buckman. (Sherborne: J. A. Ruegg, pp. 1–625, with 6 plates, 1879–1881, 8vo.)

Studi sui Ragni malesi e papuani. Per T. Thorell. II. Ragni dell' Austro-Malesia e del Capo York, contenuti nel Museo Civico di Storia Naturali di Genova. Pp. 1–720. 8vo. (Genoa, 1881.)

IF we take down part 2 of vol. i. of the earliest work of Linné's "Systema Naturæ" (1767), and wade through that marvellously incongruous order which

Digitized by Google

old naturalist contrived to group together nearly all the Arthropods known to him and which agreed almost solely in the one point of the non-possession of wings, we find under the genus "*Aranea*" only 47 species indicated, and of these only 9 are from outside Europe. In the second edition of the "Fauna Suecica" (1761) we find 33 species indicated for Scandinavia. Thus six years later all the spiders known to Linné from outside his native country amounted to 14 species! At the present time 518 species are recorded as British, and a still almost unexplored region of the Eastern Archipelago has contributed nearly as many from the researches of one or two naturalist-travellers, with whom spider-collecting was certainly not considered of first importance. And yet, notwithstanding the vast and rapid strides that arachnology has made within the twenty years past, the number of workers is still small. The subject is not always an attractive one to naturalists, and is often repugnant to non-naturalists, with whom a passion for collecting or studying spiders is seldom associated with respect for the naturalist thus smitten. But all this is rapidly changing, and no two men have done more to bring this about than the authors of the books noticed below.

In vol. xxi. p. 273, we noticed vol. i. of Mr. Pickard-Cambridge's work; vol. ii., completing it, is now before us. The whole is dedicated to John Blackwall, and the second volume must have appeared about the time of the decease of that venerable naturalist. A postscript notices some species new for the county or for Britain, and there are additional remarks on senses and economy, in which "sight," "touch and hearing," "power to utter sounds," "venom," "modes of forming snares," &c., are severally alluded to. With regard to "venom," the author expresses his firm belief that the bite of the common garden geometric spider (*Epeira diadema*) is attended by the emission of a poisonous fluid, sufficiently strong to cause visible effects on the skin of his young son, but without effect upon his own. He now agrees with the conclusion that currents of air play a great part in enabling spiders to carry their lines across from one object to another, although previously he was of opinion that the lines were carried across by the spiders themselves. As we remarked when noticing vol. i., it is a pity the author did not intercalate the descriptions of those British species not yet found in Dorsetshire amongst the others, instead of placing them in appendices at the end. This would have vastly increased the usefulness of what is still a most useful work, and while not destroying its local intentions (as indicated by the title) would have rendered it more distinctly a *Manual of British Spiders*, for such it really is. With it and Blackwall's magnificently illustrated Ray Society monograph before him, no student of our spider-fauna should be at a loss to determine, with approximate certainty, any species he may come across. The six plain plates are excellent, engraved from the author's own drawings, and representing many of the principal genera, with copious details. The index is full. The author recognises 518 species of spiders as inhabiting the British Isles, of which 373 have been found in Dorsetshire. The distribution of these amongst the several families is strikingly unequal. Thus we find three families represented by only one species each; another by only three species. On the other hand the *Theridieides* claim 267 species, the *Drassides* 56, the *Epeirides* 32, and so on. Possibly this is the first time that any thoroughly local society has undertaken to bring out a manual of a large group of British animals; so much the more to the credit of the Dorset Society for initiating so laudable a scheme. Their undertaking, so well concluded, is not of local (or even British) interest only, but will have to be considered by every European student of *Arachnida*.

In Dr. Thorell's bulky memoir (which forms vol. xxii. of the *Annali del Museo Civico di Genoa*) the author continues his studies on the Spiders of the Eastern Archipelago. The descriptions are worked out with his well-known detail and accuracy. Most of the materials result from the exploring voyages of D'Albertis and Beccari, and the flourishing society under whose auspices the volume is published deserves the highest credit for the promptness with which it is making known to the scientific world the riches acquired during the voyages of these renowned travellers. The descriptive portion is preceded by a bibliographical sketch of what was previously known from the regions, with an analytical and comparative examination of the arachnid fauna generally, still further subdivided in a series of tables at the end; 317 species are noticed as in the collection (of which 173 appeared to be new to science), viz. 252 from Austro-Malesia and 82 from Cape York, but 505 are recorded for the whole of that part of the globe, divided as follows:—*Orbitelariæ*, 162 species; *Retitelariæ*, 38; *Tubitelariæ*, 31; *Territelariæ*, 10; *Laterigradæ*, 84; *Citigradæ*, 29; and *Saltigradæ*, 151. Some idea of the riches of the fauna in this particular respect may be gathered from the fact that no less than eighteen species of the extraordinary genus *Gasteracantha* are described. We cannot resist a few words of admiration at the manner in which the publications of this Italian society are got up, the more so as the printing is done at the Deaf and Dumb Institute of Genoa (Istituto Sordo-Muti). Paper, typography, and editing alike leave nothing to be desired.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

The Oldest-known Insects

I MUST ask your permission to correct the errors into which your correspondent, Dr. Hagen, has fallen respecting the Erian (Devonian) beds near St. John, New Brunswick, holding certain fossil insects described by Dr. Scudder.

The Dadoxylon sandstone and Cordaite shale of the vicinity of St. John have been studied not only by myself, but by so good geologists as Prof. Hartt, Prof. Bailey, and Mr. Matthew, and by the officers of the Geological Survey of Canada; and their stratigraphical relations have been illustrated by maps and sections, not only in my "Acadian Geology," but in the *Reports* of the Geological Survey, more especially those for 1871 and 1875. They have, besides, been thoroughly exposed and ransacked for fossils by expensive quarrying operations undertaken by the Natural History Society of St. John, and their plants have been described and compared in detail with those of the neighbouring Carboniferous formations in my Report "On the Devo-

Digitized by Google

nian Plants of Canada," and subsequent Reports on the plants of the Lower Carboniferous and Millstone Grit formations (Geol. Survey of Canada, 1878 and 1873). In these circumstances it seems strange that the received conclusions as to their age should be termed "simple negation not supported by facts," and regarded as of no scientific value in comparison with the mere assertion of a gentleman who has no knowledge whatever of the stratigraphy of the region, and with the "authority" of Dr. Heer, who is no doubt an excellent authority on certain departments of European palæobotany, but who has not seen the beds in question, nor, so far as I am aware, studied their fossils.

The beds referred to, like the Devonian generally in Eastern Canada, underlie unconformably the lowest Carboniferous beds, a circumstance due apparently to the extensive igneous action which closed the Devonian period in this region, giving origin to masses and dykes of intrusive granite, and disturbing and partially altering the strata of Devonian and greater age, the materials of which have contributed to the Lower Carboniferous conglomerates. There is thus no question here as to any transition between Devonian and Carboniferous, and the beds holding the plants and insects are stratigraphically pre-Carboniferous.

The Lower Carboniferous beds, succeeding to the Devonian formation, and developed to the eastward of St. John, hold the characteristic flora of the Horton series, or Lowest Carboniferous, equivalent to the Culciferous or Tweedian formation of Scotland. In succession to this we have the flora of the Millstone grit, of the true Coal-Measures, and of the Permo-Carboniferous or Lower Permian. All of these have been explored and their plants catalogued and described in my own memoirs or in the reports of the Geological Survey, and it has been fully established that the flora of the Devonian beds is characteristic and distinct from any of these sub-floras of the Carboniferous.

The plants of the Cordaite shales are not only distinguishable from those of the Carboniferous found in their vicinity, but the assemblage includes forms like *Psilophyton* and *Archæopteris*, which are characteristic of the Devonian, and are not found in the Carboniferous elsewhere in America. In the Devonian of Northern New Brunswick some of these plants are associated with fishes of the genera *Cephalaspis*, *Pterichthys*, &c., well-known Devonian types.

For additional information as to the geological relations of the St. John plant beds and notices of new species, I may refer to my paper on "New Erian Plants," in the *Journal* of the Geological Society of London, vol. xxxvii., May, 1881. This paper Dr. Hagen had probably not seen at the time when his letter was written.

The particular fern in question, *Peæopteris serrulata* of Hartt, has been fully described, first by Prof. Hartt, and subsequently by myself, and its distinctness from *P. plumosa* pointed out.[1] The criticism of Dr. Hagen, as to its not appearing in the sectional lists, and still being called by me a common fern, is based on a mere accident, which I could easily have explained to him. The plants referred to as found in each layer in the detailed section are those originally described by me from these beds. Some species, subsequently recognised and described by Hartt, were not included in the sectional lists, and were referred to only in a note, because I had received no information from Prof. Hartt as to the particular layers in which they were found, though I knew that some of them were by no means uncommon, from the number of specimens obtained. Dr. Hagen criticises my figure of the species, but that does not affect the question, as I have compared the specimen on the slab with *Platyphemura* with the original specimens in my collection. My figures, however, show fairly the general form of the frond; and there is also a magnified figure of a pinnule, showing the venation, which should enable any one to recognise the species, and with the aid of the description to distinguish it from *P. plumosa*.

With regard to the "Ursa stage" of my respected friend Dr. Heer, founded on a little known and apparently exceptional locality, I have always objected to its being made a standard of comparison for the thoroughly worked and widely distributed Devonian or Erian rocks of North America. I gave some reasons for this in a paper sent to the Geological Society of London shortly after the appearance of Dr. Heer's memoir, an abstract of which appears in the *Proceedings* of the Society. It will be sufficient to say here that the grounds on which Dr. Heer refers the Devonian of New Brunswick to the Ursa stage would apply to the Chemung, and even to the Hamilton formations of the New York series.

[1] "Acadian Geology: Report on Devonian Plants." *Canadian Naturalist*, 1881.

The great richness of the Devonian of North America in plants is a very remarkable geological fact, which I regret has hitherto far exceeded the means available for its illustration. I hope, however, to remedy this to some extent on occasion of the meeting of the American Association in Montreal in 1882, when my whole collection of Erian plants, comprising those illustrating the several stages of the Carboniferous, will be exhibited in the new Peter Redpath Museum, and will show more fully than has been hitherto possible the progress of the American flora from the Silurian to the Permian. It will be a great pleasure to me if any palæobotanists who are specially attracted to the magnitude of the Devonian flora will avail themselves of this opportunity to judge for themselves, and in this way form their opinions as to the affinities and relations of the species.

McGill College, Montreal, September 1 J. W. Dawson

Sound-producing Ants

I AM glad to see my statement in NATURE, vol. xxv. p. [illegible], verified by Mr. H. O. Forbes, from Sumatra, and one more a few acts of another kind that make this parallel more complete. scratching sound, though not to the same extent. If one of the before noted, and that was thus—

i.e. three taps in unison and a pause of about a second, taps of equal duration. The ants [illegible] and [illegible] unless the exciting cause again acts, when they again set up beautiful unison. How they so correctly start together in cases of - - - ——— or the ——— — — — — — and keep tap in time, is really wonderful. White ants [illegible] rappings, but not in rhythm as far as I know, and they never call or warn. These little black ants cannot be heard unless the material they are on is sensitively sonorous. Having to place a tumbler on a sideboard lately in the dark, I was startled to hear this — — — — — — — arise from a saucer repeated it, and the noise at once convinced me that I had On getting a light I found a sheet of writing paper had been on the bowl, and was covered by them; the glass [illegible] less, I found.

Aram, July 6 S. E. Bo

[The ants sent are apparently "workers" of a [illegible] larger than a small British *Myrmica*.—ED.]

Wasps

A COUPLE of weeks ago I found on my window-pane a black wasp holding in its mandibles a plump spider about an eighth of an inch in diameter. I placed the wasp under a bell-glass and set it on my desk, where I could readily watch further developments. Finding itself in captivity, the wasp dropped its booty and spent some time in trying to find a way of escape. Coming at length to a state of rest, it seized the spider and sprang upon it with tiger-like fierceness. Seizing it, raising itself up to its full height, the wasp brought it quickly under and forward with a quick motion, and gave the spider two or three thrusts with its sting. Assured that the spider was dead, the wasp proceeded to roll it over and over, repeatedly licking it up into a globular mass. This done it seized the spider, but, foiled in the attempt, it dropped the spider, which lay for some time apparently forgotten. This whole operation was [illegible] several times repeated during the two days of my observations. Being called away from home for a few days, I was absent on my return to ascertain the results of my experiment. I had taken the precaution at the first to place under the bell-glass a small dish of clean water, to which the wasp had helped itself freely. I found the wasp dead; but not the least trace of the spider had it eaten. My conclusions are: (1) that the wasp died of starvation; (2) that the spider was intended, not as food, but for that of its young in their larval state. In confirmation of this I have broken open several of the [illegible] of these wasps, and found them filled with paste and portions of spiders, flies, and worms. Only [illegible] opportunity was afforded me for further observations in this direction. One of my flowering vines is infested with [illegible] worm—the larva of the yellow butterfly. I discovered a [illegible] and-yellow wasp standing on the edge of a leaf of the [illegible] holding fast to one of these worms of twice its own [illegible] worm was dangling in mid-air, and the wasp [illegible] riously for a long time to pull it up on the [illegible]

Digitized by Google

Failing in this, with a dexterity worthy of the Knight of the Shears it cut the worm in two, letting about three-fourths of it fall to the ground. The remainder was then easily dragged to the surface of the leaf, where the wasp spent some fifteen minutes in cutting down, trimming, and reducing it to a globular mass of about an eighth of an inch in diameter. Then resting for a few minutes, and taking a fresh hold of its booty, it flew briskly away. J. T. BROWNELL

Treatment of Hay Fever

SOME years ago Prof. Helmholtz, in a letter to you, gave an account of a remedy he had found for "hay fever." This was simply to treat the part of the nose, which seems to be the seat of the trouble, with sulphate of quinine solution by pouring it into the nose with a pipette, while lying on a sofa with the head turned upside down. Having had the most enjoyable part of summer destroyed by hay fever ever since I can remember, I have tried every remedy I have heard of, including internal doses of arsenic, and I have found them all to fail. Prof. Helmholtz's method only gives me relief for ten minutes or so, and cold water does the same. I have tried solutions of sulphate of zinc and tannin, and many other astringents, but all to no purpose. As many others knew that I was experimenting upon myself in this matter, I have had several patients trying all the remedies that I have tried, and I can therefore say with certainty that no remedy yet published will cure hay fever. I have however succeeded in finding a method which is a really effectual cure, and as I know that many are rendered miserable during the most enjoyable part of the year, I hasten to give them the benefit of the result of my inquiries. One thing which misled me was that my eyes were often very much inflamed and pained during an attack, and I often tried remedies for my eyes (which have sometimes gone wrong when I had no hay fever) when they were only affected in sympathy with my nose. I found that the only thing required was to prevent the entrance of the pollen grains into the nose. When there are not many in the air, as during or after rain, it is simply necessary to stop the nose with a spring clip. I have used a piece of brass or steel ribbon bent double, and having only sufficient spring to close the nostrils without undue pressure. This causes the patient to breathe by the mouth, but one soon gets accustomed to the inconvenience. I found that to stop the nostrils with cotton wool was far too irritating, especially as those afflicted with hay fever are so owing to the tenderness of the internal coating of the nose. When going amongst hay a further precaution must be taken, viz., plugging the ducts from the eyes. I used for this purpose dumb-bell shaped pieces of glass, which are easily slipped into the ducts, and can be removed when wanted. Thus protected, any one who is troubled by hay fever can go into the camp of the enemy and stir up hay in a field with as much impunity as one not troubled with this "sixth sense." The season for hay fever is nearly passed now, but I hope that the publication of this note will be the cause of relief to many during next summer, and on that plea I ask its publication in your valuable journal, and I hope that medical men in the South of England, where hay fever is common, will give it a trial and report upon it next summer. In Scotland hay fever is practically unknown. J. B. HANNAY

Red Rainbows

PROF. S. P. THOMPSON'S letter (p. 459) makes me recall that when on September 2 last year I crossed Wales westwardly from Hereford, on a fine sunny day, the train ran into a misty shower after 6 p.m. at Machynlleth, and out of it as we neared the viaduct at Barmouth. The sun had been obscured for some time, when it suddenly shone out through a chink between sea and cloud, causing in the east a very beautiful red rainbow. Like Prof. Thompson, I was under the impression that the phenomenon was of no uncommon occurrence, so did nothing more than note it in my diary. HENRY MUIRHEAD

Cambuslang, September 16

Infusorial Parasites on Stickleback

ONE day in June, when examining a very small stickleback under the microscope, I was surprised to find it infested by numbers of infusoria, evidently parasitic upon it. This led me to examine others from the same water, viz, a pond very rich in infusorial life generally, as also specimens from the river close at hand. Every specimen from the pond was similarly attacked, while none of those from the river were so. The parasite is apparently *Trichodina pediculus*, which is stated to be parasitic upon *Hydra vulgaris*. Want of literature on the subject has prevented me from following the matter up, but it seems that I have found, if not a new species, at least a new host for a known species. I shall be glad if any of the readers of NATURE can give me any information on the subject. N. H. POOLE

Charterhouse, Godalming

Photographing Diffraction Rings—Optical Phenomenon

THE peculiar character of the photographs of an opening to the sky in the dark Cyclopean gallery at Tiryns, to which Mr. W. J. Stillman calls attention (NATURE, vol. xxiv. p. 260), finds an obvious explanation in the well-known optical phenomenon of diffraction rings, produced when a beam of light is transmitted through a small circular aperture, and viewed by means of a lens. Had your "Cecropian" correspondent examined the image of the illuminated opening by the assistance of a lens, the phenomenon of concentric coloured rings would, doubtless, have been recognisable to the eye. Hence the only point of interest in the phenomenon observed by Mr. Stillman is the significant fact that in securing the fleeting images of the rings on the gelatine plate—the actinic rays being alone effective—alternate dark and bright concentric rings are produced, as in the case of homogeneous or monochromatic light, instead of the coloured rings seen by interposing a lens between the aperture and the eye. In other terms, the impressions on the gelatine plate being due to the action of the monochromatic actinic rays, the theory of diffraction shows that the concentric rings should be alternately dark and bright. This is an important circumstance in the applications of photography to such investigations.

Berkeley, California, August 16 JOHN LE CONTE

A Primitive Diving-Bell

IN NATURE, vol. xxiv. p. 201, it is stated that Herr Budde has found a description of a primitive diving-bell in a work of Bartolini, 1674. The inventor appears to have been Franciscus Kesler, 1616. This description of Kesler's diving machine will also be found, together with representations of the same, in Schwenter's "Deliciæ Physico-Mathematicæ," 1636, a very rare and curious volume; so rare indeed that it is stated in *Cosmos*, January 27, 1860, "it is not to be found in the Imperial Library, nor in any of the public libraries of Paris." J. van Lennep, in *Notes and Queries*, December 15, 1859, p. 503, says "there is a Dutch translation of Schwenter, 1672; of this rare volume I fortunately possess a copy." N. S. HEINEKEN

Sidmouth, September 11

ITTAVIO LAUDI.—Messrs. Trübner, publishers, London, might be able to help you to get copies of the Chinese translations mentioned in Mr. Fryer's articles on "Science in China."

FREDERICK CURREY, M.A., F.R.S.

THE late Frederick Currey, whose death was announced in last week's NATURE, p. 475, was born at Eltham on August 4, 1819, educated at Eton and Trinity College, Cambridge, there obtaining a scholarship, and attaining his B.A. in 1841; three years later he proceeded to M.A., and was called to the Bar, afterwards practising as conveyancer and equity draughtsman.

His first public performance as a scientific writer was a translation of Schach's "Das Mikroskop" in 1853, a second edition of which was called for within two years. In the *Microscopical Journal* for 1854 he published some observations on two new fungi, and by the same channel he afterwards communicated several papers, chiefly on the obscure points in the reproduction of the lower cryptogams. The Greenwich Natural History Club was established in 1852, Mr. Currey being one of the earliest members, and the next year he read a paper on the

Digitized by Google

"Fungi of the Neighbourhood of Greenwich," which was printed in the fifth volume of the *Phytologist*. In 1857 a committee of that Club was appointed to draw up a report on the flora of the district; Mr. Currey was chosen its chairman, and drafted the report, which enumerated 395 fungi. In that year he contributed a paper to the Royal Society, which was printed in the *Proceedings*, On the Occurrence of Amorphous Starch in a Tuberaceous Fungus, a point of much interest, as starch is rarely found in fungi. He was elected Fellow of the Linnean Society in 1856, and in 1858 Fellow of the Royal Society also; in 1860 he was appointed secretary of the former society in succession to Mr. J. J. Bennett, a post which he held until 1880, when he relinquished that office and acceded to the less arduous duties of treasurer, retaining that appointment until his death. In 1862 the Ray Society issued a translation, with considerable additions, from Hofmeister, entitled "On the Germination, Development, and Fructification of the Higher Cryptogamia," a task which Mr. Currey undertook in 1859; the following year he edited a second edition of Dr. Badham's "Esculent Funguses of England," in which he made as few alterations as possible. Several papers on mycological subjects appear in the *Transactions* of the Linnean Society, which will be found in the "Catalogue of Scientific Papers," under his name, his last contribution being, "On a Collection of Fungi made by Mr. Sulpiz Kurz," in 1876.

By his death the Linnean Society has lost an experienced officer, and its members a valued friend whose place it will be hard to fill.

THE AMERICAN ASSOCIATION

THE thirtieth meeting of the American Association for the Advancement of Science commenced at Cincinnati on August 16. Always a hot place in summer, the temperature at Cincinnati during the past two months has been at intervals unusually high, running above 100° for several days together. This and the fear of its recurrence no doubt induced many to stay away who would otherwise have been present. However, a goodly number —over 400—of new members were enrolled, and many papers of interest were read. Some of the visitors from the Eastern States were amazed to find that Cincinnati was not a little backwoods town, but a city deserving in many ways the title she claims, "The Queen City of the West." The ignorance of many of the inhabitants of the Eastern States in regard to the West is only equalled by the ignorance of Europeans in regard to America generally.

The citizens of Cincinnati exerted themselves to welcome their guests, and did it well. Their bodily wants were amply supplied, and this, to those coming from a distance and being strangers, was a matter of no small moment. Visitors known or bearing introductions were in very many cases entertained privately, and a free lunch was provided by subscription for all members daily from 1 to 2.30 p.m. The Western Union Telegraph Company, whose wires extend over almost the whole Union, gave the members the use of their lines for communication with their families, free of charge, at whatever distance they might be situated. Connection was made by telephone between the hall of meeting and the Central Telegraph Office, and between the various rooms in the building, so that it was possible to send a message without leaving the building—to ask, for example, what paper was being read in any other section. The City and Suburban Telegraph and Telephone Companies also extended the same privileges to members of the Association. The various Express Companies offered to convey light parcels containing specimens for them, free of charge, between their homes and the place of meeting, and heavy ones at low rates. Of course there was a post-office and a parcels office in the hall, with convenience and materials for writing. There was however a little deficiency in finger placards to direct strangers over the great building in which the meetings were held—the new music hall.

Besides the above, an excursion was arranged for Saturday afternoon to the Zoological Garden, one of the best in the country, and capable, if well supported, of becoming *the* best. Free transportation through the streets by the horse cars was provided, and a sumptuous repast prepared for the visitors before leaving. In the same way the Anthropological Section and others were taken out to Madisonville, about ten miles from the city, on Monday to see a prehistoric cemetery recently discovered from which several hundred skeletons, uncounted arrow-points, animal bones, horns, and teeth, and pieces of pottery have been exhumed during the past two years. The train stopped at the place to set them down, and again on its return to take them up. After the adjournment of the meeting an excursion was arranged to the Mammoth Cave, about 150 miles distant, and another to Chattanooga, about 300 miles over the new Southern Railway, both free so far as the travelling was concerned.

It will be evident that Cincinnati did her best to entertain her scientific visitors, and the latter carried away pleasant and lasting impressions of the city where the fifth and the thirtieth meetings of the Association were held, the latter having been one of the most successful in its history.

E. W. CLAYPOLE

Another correspondent writes:—

The Cincinnati meeting proved to be one of the best ever held by the Association. In attendance of members it was much surpassed by the Boston meeting last year, which reached the phenomenal number of 997; the number at Cincinnati was about 550, being more than double that at any previous meeting in the West. Over 400 persons joined the Association. Nearly 200 papers were presented; it is not derogatory to any author to say that these papers were of average interest only, and comprised no startling announcements. The general management was very successful. The chief feature of the meeting was the adoption of the important changes in the constitution which are expected to simplify business in the future. If any complaint can be made, it is of the rather generous disposition on the part of the Sectional Committees towards authors whose productions are of doubtful novelty and uncertain value. There is a tendency also to overrun the allotted time; papers for which twenty-five minutes are asked consume seventy minutes, and those of ten minutes extend to thirty minutes. The remedy of this evil lies with the chairmen of the sections, and it is hoped that they will hereafter exert their powers more frequently. The social features of the meeting were very enjoyable; the reception at Highland House, and the daily lunches served in the Exhibition building brought together citizens and members in pleasant intercourse.

Prof. Wm. B. Rogers of Boston, the first presiding officer of the Association, was elected an Honorary Fellow, on the unanimous recommendation of both Sections A and B. Prof. Rogers is the first Honorary Fellow chosen by the Association.

The amendments to the constitution proposed at the Boston meeting were adopted almost unanimously. They provide for the formation of nine sections, as follows:—A, Mathematics and Astronomy; B, Physics; C, Chemistry; D, Mechanical Science; E, Geology and Geography; F, Biology; G, Histology and Microscopy; H, Anthropology; I, Economic Science and Statistics.

Each of the above Sections is to have its own chairman, who is also Vice-President of the Society, and its own Secretary. The amended constitution also creates the office of Assistant-General Secretary, makes certain changes in the composition of the Standing Committee.

Digitized by Google

and of the nominating committee. These alterations make the organisation more like that of the British Association for the Advancement of Science, and became necessary on account of the recent rapid growth of the Association. The membership has doubled within two years, being now about 1800.

The recommendation of the Standing Committee to meet in 1882 at Montreal was adopted with acclamation. The invitation from Minneapolis for 1883 was referred to the Standing Committee.

The Association elected Dr. J. W. Dawson of Montreal President for the ensuing year. The time of meeting was fixed for the fourth Wednesday in August, 1882. Nearly seventy Fellows were elected by ballot, and the following officers for 1882, in accordance with the recommendation of the Nominating Committee, were unanimously elected :—

Officers for 1882. Vice-presidents : Section A, Mathematics and Astronomy, Prof. William Harkness, U.S.N.; Section B, Physics, Prof. T. C. Mendenhall of Columbus; Section C, Chemistry, Prof. H. Carrington Bolton, Ph.D., of Hartford, Conn.; Section D, Mechanical Science, Prof. W. P. Trowbridge, Ph.D., of Columbia College, New York; Section E, Geology, Prof. E. T. Cox of San Francisco; Section F, Biology, Capt. W. H. Dall of Washington, D.C.; Section G, Histology and Microscopy, Prof. A. H. Tuttle of Columbus, Ohio; Section H, Anthropology, Prof. Daniel Wilson of Toronto; Section I, Economic Science and Statistics, E. B. Elliot of Washington, D.C.

We have already (vol. xxiv. p. 455) referred to the action taken by the Association in reference to science degrees.

The following are some of the principal papers read at the meeting :—

In Section A : Magnetic survey of Missouri, by Prof. F. E. Nipher; on the methods of determining the solar parallax with special reference to the coming transit of Venus, by Prof. William Harkness; on the wave-lengths of the principal lines of the solar spectrum, by Prof. T. C. Mendenhall; experiments to determine the comparative strength of globes and cylinders of the same diameter and thickness of sides, by Samuel Marsden; historic notes on cosmic physiology, by Dr. T. Sterry Hunt; upon the use of the induction balance as a means of determining the location of leaden bullets imbedded in the human body, by Prof. Alex. Graham Bell; upon a new form of electric probe, by the same; on a new method of applying water-power of small head to effect the direct compression of air to any required high pressure, by Prof. H. T. Eddy; the needle telephone, a new instrument by Dr. Goodman of Louisville, Ky., by Dr. J. Lawrence Smith; an improved sonometer, by W. Le Conte Stevens; on the great outburst in comet *b*, 1881, observed at the Cincinnati Observatory, by Prof. Ormond Stone; method of determining the value of the solar parallax from meridian observations of Mars, by Prof. J. R. Eastman; numbers of cometary orbits relative to perihelion distance, by Prof. H. A. Newton; numerical elements of the orbits of the seven electrical vortices to whose motions atmospheric storms are principally due, with the processes by which they have been derived, and examples given of the application of the formula by which their positions on the surface of the earth can be computed for any given time, by Thomas Bassnett; a preliminary investigation of the two causes of lateral deviation of spherical projectiles, based on the kinetic theory of gases, by Prof. H. T. Eddy; note on the theory of the flight of elongated projectiles, by Prof. H. T. Eddy; on the mechanical principles involved in the flight of the boomerang, by Prof. H. T. Eddy; the electrophore and electric lighting, by Mr. E. B. Elliott; nodular concretions in meteoric iron, bearing on the origin of same, by Dr. J. Lawrence Smith; an anomalous magnetic property of a specimen of iron, by Dr. J. Lawrence Smith; on the errors to which self-registering clinical thermometers are liable, by Dr. Leonard Waldo; a new radiometer, by Dr. H. Carmichael; a new differential thermometer, by Dr. H. Carmichael; note on an experimental determination of the value of π, by Prof. T. C. Mendenhall; remarks upon, and an exhibition of, Japanese magic mirrors, by the same; on standard time, by E. B. Elliott; note on a comparison of Newcomb's tables of Uranus and Neptune, with those of the same planets by Leverrier, by D. P. Todd; universal energy of light, by Pliny Earle Chase; electricity, magnetism, gravitation—their phenomena considered as the manifestations of one force, by S. S. Parsons.

In Section B : On the influence of the structure of the nerve-fibres upon the production and conduction of nerve-force, by H. D. Schmidt; on the action of pilocarpin in changing the colour of the human hair, by Dr. D. W. Prentiss; the unification of geological nomenclature, by Dr. R. Owen; the life-unit in plants, by Prof. B. D. Halsted; recent discoveries, measurements, and temperature observations made in Mammoth Cave, Ky., by Rev. H. C. Hovey; influence of forests upon streams, by David D. Thompson; note on the segmentation of the vertebrate body, by Charles Sedgwick Minot; phenomena of growth in plants, by D. P. Penhallow; the recurrence of faunas in the Devonian rocks of New York, by H. S. Williams; a contribution to Croll's theory of secular climatal changes, by W. J. McGee; the evidence from the drift of Ohio in regard to the origin of Lake Erie, by E. W. Claypole; on some relations of birds and insects, by S. A. Forbes; Niagara River, its cañon, depth, and wear, by Wm. Hosea Ballou; evolution and its place in geology, by Edward S. Edmunds.

In Section C : Is the law of repetition the dynamic law underlying the science of chemistry? by Miss V. K. Bowers; evidences of atomic motion within molecules in liquids, as based upon the speed of chemical action, by Prof. R. B. Warder; the constitution of the "atom" of science, by Mrs. A. B. Blackwell; the sources of nitrogen in plants, by Prof. W. O. Atwater; notes in experimental chemistry, by Prof. A. B. Prescott; determination of phosphorus in iron, by Dr. J. Lawrence Smith; the liquefaction of glass in contact with water at 250° C., by Prof. H. Carmichael; the chemistry of fish and invertebrates, by Prof. W. O. Atwater; notes in experimental chemistry, by Prof. Albert B. Prescott; the quantitative estimation of nitrogen, by Prof. W. O. Atwater; the quantitative estimation of chlorine, by Prof. W. O. Atwater; the nitrogenous constituents of grasses, by Clifford Richardson.

In Section D (Anthropology) : Animal myths of the Iroquois, by Mrs. Erminnie A. Smith; antiquity of man in America, by W. de Haas; progress of archæological research, by W. de Haas; the mound builders : an inquiry into their assumed southern origin, by W. de Haas.

In Section E (Microscopy) : On a convenient method of expressing micrometrically the relation between English and metric units of length on the same scale, by William A. Rogers and George F. Ballou.

In Section F (Entomology) ; On the length of life of butterflies, by Prof. W. H. Edwards; on the life duration of the Heterocera (moths), by Prof. J. A. Lintner; how does the bee extend its tongue? by A. J. Cook; the egg-case of *Hydrophilus triangularis*, by Dr. C. V. Riley; on the oviposition of *Prodoxus decipiens*, by the same; the cocoon of Gyrinus, by the same; suggestions of co-operation in furthering the study of entomology, by Prof. B. P. Mann.

THE BRITISH ASSOCIATION

REPORTS

Report of the Committee on Tidal Observations in the English Channel and the North Sea, by J. N. Shoolbred.—In the report it was stated that no official reply had been received by the Committee as to having an international datum for observations, or as to maritime governments giving facilities for detailed observations. The Committee urged the desirability of carrying out a series of observations on the Azores. The Portuguese Government had established a station for registering tides, as had also our own Government at Dover. The Committee hoped before long to have a series of observations giving most important results.

Report of the Committee for Underground Temperature, by Prof. Everett.—In the report it was stated that the temperature varied from one degree for 30 feet to one degree for 100 feet in going down beneath the surface of the earth in different places. During the past year observations have been made in the East Manchester coal field, the Talavgoch lead mine, Flintshire, and at the Radstock collieries, Bath. With regard to the observations in the East Manchester coal-field, these were respectively

Digitized by Google

taken at Ashton Moss, Bredbury, and Nook Pit: the temperatures were as follows:—

Place	Depth. Feet.	Temperature. °
Ashton Moss	2790	85·3
Bredbury Colliery	1020	62·0
Nook Pit	1050	62·3

The increments of temperature would be as follows:—

Place.	Depth. Feet.	Increase of temperature.
Ashton Moss	2790	36·3
Bredbury Colliery	1020	13
Nook Pit	1050	13·3

This gave for each degree of increase, Ashton Moss 76·9 feet, Bredbury 78·5, and Nook Pit, 79 feet. In Flintshire the observations showed great irregularity last year, and the observations taken this year increased the irregularity. The observations were taken at a place in the lead mine at a depth of 660 feet; at this depth the temperature was 62°, 48° being assumed to be the surface temperature which gave an increase of 14° in 660 feet, or 1° in 47 feet. At the Radstock colliery observations were made at three places. The Wells May Pit, 500 feet deep, the Ludlow Pit, 1000 feet, and a third station in the same pit 810 feet deep, the surface temperature being assumed 50°, the rate of increase was found to be 11°·7 in 500 feet, and 13° for both 810 feet and 1000 feet.

Mr. W. M. Hicks read his report *On Recent Progress in Hydrodynamics*, which he related to the investigations undertaken since 1846, the date of Prof. Stokes's well-known report.

A Report of the Committee on Fundamental Invariants, by Prof. Sylvester, was read.

Report of Committee on Mathematical Tables, by James Glaisher, F.R.S.—The author stated that the factor table for the sixth million was now completed and stereotyped, and he had the pleasure to exhibit to the section proofs of the whole of this million taken from the stereotyped plates. The factor tables for the fourth and fifth millions had been already published, so that now the gap of three millions between the tables of Burckhardt (1817) and those of Dase (1861) was completely filled up. The introduction to the sixth million would shortly be completed, when this volume would appear.

Report on the Tertiary Flora of the Basalt of the North of Ireland, drawn up and illustrated by W. H. Bailey, Geological Survey of Ireland.

Mr. Sclater, in the absence of Mr. Thiselton Dyer, presented the *Report of the Committee appointed for the Purpose of Investigating the Natural History of Timor-laut*.—In a letter addressed to Sir Joseph Hooker, director of the Royal Gardens, Kew, Mr. H. O. Forbes had written from Sumatra, offering, if some assistance could be forwarded to him, to attempt an expedition to Timor-laut, for the purpose of investigating its natural history —"an object," as Mr. Forbes stated, "the accomplishment of which is desired both by botanists and zoologists." An application on Mr. Forbes's behalf was accordingly made to the British Association, and a sum of 50*l*. was voted by the General Committee at the Swansea Meeting to be placed at the disposal of the Committee, to whom the conduct of the matter was intrusted. The action taken by the Association was communicated to Mr. Forbes, and a letter was received in reply. This was the most recent information which the Committee possessed as to his plans. It was somewhat doubtful whether, owing to insufficiency of funds, he was able to start. At any rate, the grant made at Swansea remained in the hands of the Committee. The expedition was obviously attended with some difficulty, if not danger. Its success must be largely dependent on fortunate accident. The Committee, however, thought that there was a reasonable chance of the work being done, and therefore recommended their reappointment, and that a further sum of 100*l*. be placed at their disposal.

The *Report of the Committee on the Natural History of Sawtra* gave an account of the progress made in working out Prof. Bayley Balfour's collections, and recommended its reappointment with a somewhat extended sphere, so as to embrace the adjoining highlands of Arabia and Somali Land.

A Report by Mr. R. J. Usher *On Caves and Kitchen-Middens at Cappagh, County Waterford*, described an extensive series of kitchen-middens which had been excavated with the aid of the Association grant. One of these filled a [illegible] extent, the more ancient parts of which [illegible] explored. The excavated parts yielded large [illegible] and implements which did not furnish very evidential [illegible].

The *Report of the Committee for the Investigation of the Influence of Bodily Exercise on the Elimination of Waste*, presented by Mr. North, detailed the delays in [illegible] investigation, owing to the necessary devising and [illegible] instruments. It was hoped however that valuable results might be obtained before the meeting at Southampton.

The *Report of the Committee on the Zoological Station at Naples* was read by Mr. Percy Sladen. He stated that the laboratory had added micro-spectroscopic and polariscopic apparatus, one of Du Bois-Reymond's section apparatus, and a valuable series of chemico-physiological apparatus; and the lending and working apparatus have been successfully worked. Two of the monographs of the Fauna and Flora of the Gulf of Naples have been published in the last year, viz., the Ctenophora by Dr. Carl Chun, and the species of the genus Pterotrachea by Dr. Carl Emery. The monographs on the Pantopoda, by Dr. Dohrn, and the Corallines, by Solms-Laubach; and on Balanoglossus, by Dr. J. W. Spengel, are in a forward state. The "Neapel Fahresberichte" for 1880 is in the press, and will be issued in two parts. The novel method of investigating the rich fauna by means of diving apparatus has been successfully used in the clear portions of the bed near Naples. Many details of improvement have been made, and many features and districts to be explored which are inaccessible to the trawl or the dredge and sponges, hydroids, actiniæ, bryozoa and plants, with branchs and algæ may be obtained *in situ*. During the year Mr. Allen Harker has studied at the British Association table chiefly on the circulation and respiration in the polychæte annelids; also Mr. F. G. Penrose, who investigated the question in *Salen legumen*. Mr. P. Geddes desires to prosecute special researches during the coming years, and will be accompanied by an assistant. Thirty-four naturalists have worked at the station during the year, many memoirs have been published, large quantities of specimens have been sent to foreign museums and naturalists, as well as micro copical preparations.

Report of the Committee, consisting of Mr. Thos. Jones, F.R.S., Mr. William Shaen, Mr. Stephen Hourey, Mr. John Wilkinson, the Rev. W. Delany, Mr. N. Story Maskelyne, M.P., F.R.S., Dr. Sullivan, E. Thompson, Miss Lydia E. Becker, Sir John Lubbock, Bart., M.P., F.R.S., Prof. A. W. Williamson, F.R.S., Mrs. Augusta Webster, and Dr. J. H. Gladstone, F.R.S. (Secretary), on the manner in which Rudimentary Science should be taught, and how Examinations should be held therein Elementary Schools.—Rudimentary science is taught in public elementary schools in the form of—I. Object lessons; II. Science subjects under article 19, c. v. of the New Code; III. Specific subjects under Schedule IV. of the same Code; IV. Science subjects preparatory to entering classes in connection with science schools.

I. Object lessons are attempted in a large number of infant schools, and in some instances are very effective in developing the perceptive powers and intelligence of the children; in other cases they are too formal, and left too much to the young teachers. In boys' and girls' schools they frequently appear upon the time table, especially where, as in the schools of the London Board, they are looked upon as a necessary part of the instruction; but they are generally given in an unsatisfactory and often in an unsatisfactory manner.

II. The teaching of science as a class subject under the Code only commenced last October, and thus no examinations have yet been held under it. Note al history, physical geography, natural philosophy, &c., are mentioned in article 19, c. v., and it is stated that the instruction should be given "through really good lessons, illustrated, if necessary, by maps, diagrams, specimens, &c."; but the teachers are limited to two subjects, and the old subjects, grammar, history, geography, and needlework naturally retain their place in the great majority of the schools. Science reading-books for these rudimentary schools have scarcely yet come into existence.

III. The specific subjects of the fourth schedule include mechanics, animal physiology, physical geography, [illegible] domestic economy, but only two subjects may be taken [illegible] if the child has passed Standard VI.); and the schools [illegible] includes English literature, mathematics, Latin, French, [illegible] German. Literature is a general favourite, and [illegible]

Digitized by Google

economy is obligatory in girls' schools if any specific subject is taken at all; so that the chance of any of the others being introduced is very much diminished. It must also be remembered that these subjects are only allowed to be taught to children in the Fourth Standard and upwards; while only about one-fifth of the children in the boys' and girls' schools are to be found at present in these standards. According to the Report of the Committee of Council for Education recently issued, there were 476,761 children presented for examination in these standards, of whom the following numbers only were examined in the science subjects:—

Mechanics	2,109
Animal physiology	24,725
Physical geography	34,288
Botany	1,853
Domestic economy	50,797

Out of 489 boys' and girls' departments under the London School Board, the specific science subjects were taken up, as follows, during the year 1880:—

Mechanics in	4 departments
Animal physiology in	123 ,,
Physical geography in	112 ,,
Botany in	9 ,,
Domestic economy	172 ,,

Mr. Hance of the Liverpool School Board has favoured us with an account of the systematic scientific instruction which is given in the Board schools of that town by a special science staff. The subject selected for the boys is mechanics as defined in the New Code, with a considerable development in the direction of elementary physics. It has been in operation since 1877, and the results for the year 1880-81 are given in the following table:—

Year 1880-81.	Number presented.	Number passed.	Percentage of passes.
Stage I.	797 ...	442 ...	55·46
,, II.	398 ...	261 ...	65·59
,, III.... ...	122 ...	82 ...	67·21
Total... ...	1317 ...	785	59·6

Domestic economy is also taught to the girls in a similar manner. In Birmingham 1200 scholars are receiving scientific instruction in the schools of the Board, and it is stated that the teachers uniformly find that "it added interest to the work of the school, that the children were eager to be present, and that the lessons were enjoyed, and were in fact giving new life to the schools." The Board have found the results so satisfactory that they are now furnishing their newest school with a laboratory and lecture room.

IV. As to science-teaching which does not fall under the provisions of the New Code it is not probable that any large amount is attempted. In Manchester, however, the Board gives instruction to 404 children, all of whom have passed Standard VI., the highest ordinary standard, in the following subjects: physiology; acoustics, light, and heat; magnetism and electricity; chemistry; practical chemistry; botany. This teaching is illustrated by means of good apparatus, &c., and has had a very beneficial effect upon the science and art classes of the town. When it is considered that the provisions of the Code naturally form, in almost all cases, the extreme limit of what will be attempted in the schools, it is important that they should be placed as high as possible. This will be a great advantage to the stronger schools, and no disadvantage to the weaker ones, as the higher branches of science-teaching will of course be optional. Your committee have, therefore, arrived at the following conclusions:—

I. *As to object lessons.* That it is very desirable that Her Majesty's Inspectors should take object lessons into account in estimating the teaching given in an infant school; and that they should examine the classes in the graded schools wherever object lessons are given.

II. *As to class subjects.* That the teaching of such subjects as natural history, physical geography, natural philosophy, &c., should not necessarily be "through reading lessons," as oral lessons, "illustrated by maps, diagrams, specimens, &c.," are undoubtedly better when given by a teacher duly qualified to handle these subjects. They are of opinion, also, that it will be desirable to allow a larger number of class subjects to be taken up in any particular school, and to give in such case a proportionately increased grant.

III. *As to specific science subjects.* That a knowledge of the facts of nature is an essential part of the education of every child, and that it should be given continuously during the whole of school life from the baby class to the highest standard. Of course in early years this teaching will be very rudimentary; but by developing the child's powers of perception and comparison it will prepare it for a gradual extension of such knowledge. They consider also that the early teaching must be very general, while the later may be more specific; they think, however, that the science subjects as given in Schedule IV. are fairly open to objection, as being somewhat too ambitious in their nomenclature and in their scope, and that they ought not to be attempted unless the child has had a previous training in natural knowledge before entering the fourth standard. Thus the specific scientific subjects ought not to be distinct, as they practically are at present, from the previous teaching; greater latitude of choice might be allowed in them; and while they should not afford technical instruction they should prepare the way for any technical classes or schools into which the children may subsequently enter. In regard to domestic economy they are of opinion that most of the points embraced in the schedule would be useful to boys as well as to girls.

IV. *As to examinations.* That in the appointment of Her Majesty's Inspectors some knowledge of natural science should be considered as absolutely requisite; that in examining the children they should direct their inquiries so as to elicit not so much their knowledge of special facts as their intelligent acquaintance with the world of nature around them; and that this may be much better done by oral examination than by paper work.

SECTION A—MATHEMATICAL AND PHYSICAL

On the Economy of Metal in Conductors of Electricity, by Sir W. Thomson.—The most economical size of the copper conductor for the electric transmission of energy, whether for the electric light or for the performance of mechanical work, would be found by comparing the annual interest of the money value of the copper with the money value of the energy lost in it annually in the heat generated in it by the electric current. The money value of a stated amount of energy had not yet begun to appear in the City price lists. If 10*l.* were taken as the par value of a horse-power night and day for a year, and allowing for the actual value being greater or less (it might be very much greater or very much less) according to circumstances, it was easy to estimate the right quantity of metal to be put into the conductor to convey a current of any stated strength, such as the ordinary strength of current for the powerful arc light, or the ten-fold strength current (of 240 webers) which he (Sir William Thomson) had referred to in his address as practically suitable for delivering 21,000 horse-power of Niagara at 300 miles from the fall. He remarked that (contrary to a very prevalent impression and belief) the gauge to be chosen for the conductor does not depend on the length of it through which the energy is to be transmitted. It depends solely on the strength of the current to be used, supposing the cost of the metal and of a unit of energy to be determined. Let A be the sectional area of the conductor; s the specific resistance (according to bulk) of the metal; and c the strength of the current to be used. The energy converted into heat and so lost, per second per centimetre, is sc^2/A ergs. Let p be the proportion of the whole time during which, in the course of a year, this current is kept flowing. There being $31\frac{1}{2}$ million seconds in a year, the loss of energy per annum is

$$31{\cdot}5\times10^6 psc^2/A \text{ ergs} \quad . \quad . \quad . \quad (1)$$

The cost of this, if E be the cost of an erg, is

$$31{\cdot}5\times10^6 psc^2 E/A \quad . \quad . \quad . \quad (2)$$

Let V be the money value of the metal per cubic centimetre. The cost of possessing it, per centimetre of length of the wire, at 5 per cent. per annum, is

$$VA/20 \quad . \quad . \quad . \quad . \quad (3)$$

Hence the whole annual cost, by interest on the value of the metal, and by loss of energy in it, is

$$\frac{1}{20}VA+\frac{31{\cdot}5\times10^6 psc^2E}{A} \quad . \quad . \quad . \quad (4)$$

The amount of A to make this a minimum (which is also that which makes the two constituents of the loss equal) is as follows:—

$$A=\sqrt{\left(31{\cdot}5\,.\,10^6 psc^2E/\frac{V}{20}\right)}$$
$$=c\sqrt{(63\,.\,10^7 psE/V)} \quad . \quad . \quad (5)$$

Digitized by Google

Taking 70*l.* per ton as the price of copper of high conductivity (known as "conductivity copper" in the metal market), we have ·00007*l.* as the price of a gramme. Multiplying this by 8·9 (the specific gravity of copper), we find, as the price of a cubic centimetre,

$$V = \cdot 00062l. \quad . \quad . \quad . \quad (6)$$

and the assumption of 10*l.* as the par value of one horse-power day and night for 365 days gives, as the price of an erg,

$$10l./(31\tfrac{1}{2}\times 10^6\times 74\times 10^8) = \frac{1}{23\times 10^{14}} \text{ of } 1l. \quad (7)$$

Supposing the actual price to be at the rate of $e\times 10l.$ for the horse-power year, we have

$$E = \frac{e}{23\times 10^{14}} \text{ of } 1l. \quad . \quad . \quad . \quad (8)$$

Lastly, for the specific resistance of copper we have

$$s = 1640 \quad . \quad . \quad . \quad . \quad (9)$$

Using (8) and (9) in (5) we find,

$$A = c\sqrt{\frac{63\times 10^7\times 1640\times pe}{23\times 10^{15}\times \cdot 00002}} = c\sqrt{\frac{pe}{1\cdot 38}} \quad . \quad (10)$$

Suppose, for example, $p = \cdot 5$ (that is, electric work through the conductor for twelve hours of every day of the year to be provided for), and $e = 1$. These supppositions correspond fairly well to ordinary electric transmission of energy in towns for light, according to present arrangements. We have—

$$A = c\sqrt{\frac{1}{27\cdot 6}} = \frac{c}{5\cdot 25} \doteq \cdot 19c.$$

That is to say, the sectional area of the wire in centimetres ought to be about a fiftieth of the strength of the current in webers. Thus, for a powerful arc-light current of 21 webers, the sectional area of the leading wire should be ·4 of a square centimetre, and therefore its diameter (if it is a solid round wire) should be ·71 of a centimetre. If we take $e = \frac{1}{11\cdot 8}$, which corresponds to 1900*l.* a year as the cost of 5250 horse-power (see Presidential Address, Section A), and if we take $p = 1$, that is, reckon for continued night and day electric work through the conductor, we have—

$$A = \frac{c}{\sqrt{381}} \doteq \frac{c}{19\cdot 5};$$

and if $c = 24$, $A = 1\cdot 24$, which makes the diameter 1·26 centimetres, or half an inch (as stated in the Presidential Address). But even at Niagara it is not probable that the cost of an erg can be as small as $\frac{1}{118}$ of what we have taken as the par value for England; and probably therefore a larger diameter for the wire than ½ inch will be better economy if so large a current as 240 webers is to be conducted by it.

Illuminating Powers of Incandescent Vacuum Lamps with Measured Potentials and Measured Currents, by Sir William Thomson and James T. Bottomley.—The electromotive force used in these experiments was derived from Faure secondary batteries, kindly supplied for the purpose by the Société la Force et la Lumière in their London office. Two galvanometers were used simultaneously, one (called the *potential galvanometer*) for measuring the difference of potentials between the two terminals of the lamp, the other (called the current galvanometer) for measuring the whole strength of the current through the lamp. The potential galvanometer had for its coil several thousand metres of No. 50 (B.W.G.) silk-covered wire (of which the copper weighs about one-twentieth gramme per metre, and therefore has resistance of about 3 ohms per metre). Its electrodes were applied direct on the platinum terminals of the lamp. The current galvanometer had for its coil a single circle, of about 10 centimetres diameter, of thick wire placed in the direct circuit of the lamp, by means of electrodes kept close together to a sufficient distance from the galvanometer to insure no sensible action on the needle except from the circle itself. The directive force on the needle which was produced by a large semicircular horseshoe magnet of small sectional area was about 2½ c.g.s., or fifteen times the earth's horizontal magnetic force in London. This arrangement would have been better for the potential galvanometer also than the plan actually used for it, which need not be described here. The scale of each galvanometer was graduated according to the natural tangent of the angle of deflection, so that the strength of the current was simply proportional to the number read on the scale in each case. Three lamps were used, Nos. II. and III. of a larger size than No. I. The experiment was continued with higher and higher potentials on each lamp till its carbon broke. The illuminating power was measured in the simplest and easiest way (which is also the most accurate and trustworthy), by letting the standard light and the lamp to be measured shed their lights nearly in the same direction on a white ground (a piece of white paper was used); and comparing the shadows of a suitable object (a pencil was used); and varying the distance of the standard light from the white ground till the illuminations of the two shadows were judged equal. The standard used was a regulation "standard candle," burning 120 grains of wax in the hour. The burning was not actually tested by weighing, but it was no doubt very nearly right; nearly enough for our purpose, which was an approximate determination of the illuminating powers of each lamp through a wide range of electric power applied to it. The following results were obtained:—

LAMP No. I.

No. of experiment.	Cells.	Volts.	Webers.	Volts × webers ÷ 10 = kilogram-metres.	Horse-power.	Candles	Candles per horse-power.

Some of the irregularities of the results in the preceding tables are very interesting and important, as showing the effect of the

Digitized by Google

blackening of the glass by volatilisation of the carbon when too high electric power came to be applied. The durability of the lamp at any particular power must be tested by months' experience before the proper intensity for economy can be determined.

On some Uses of Faure's Accumulator in connection with Lighting by Electricity, by Sir W. Thomson.—The largest use of Faure's accumulator in electric lighting was to allow steam or other motive power and dynamos to work economically all day, or throughout the twenty-four hours where the circumstances were such as to render this economical, and storing up energy to be drawn upon when the light was required. There was also a very valuable use of the accumulator in its application as an adjunct to the dynamo, regulating the light-giving current and storing up an irregular surplus in such a manner that stoppage of the engine would not stop the light, but only reduce it slightly, and that there would always be a good residue of two or three hours' supply of full lighting power, or a supply for eight or ten hours of light for a diminished number of lamps. He showed an automatic instrument which he had designed and constructed to break and make the circuit between the Faure battery and the dynamo, so as automatically to fulfil the conditions described in the paper. This instrument also guarded the coils of the dynamo from damage, and the accumulator battery from loss, by the current flowing back, if at any moment the electro-motive force of the dynamo flagged so much as to be overpowered by the battery.

An Analysis of Relationships, by Dr. A. Macfarlane.—The paper contained a summary of the notation and elementary laws of an analytical method of dealing with such questions as, in the simplest cases, may be dealt with graphically by means of the genealogical tree. The subject is a special branch of the algebra of logic, and its development appears to the author to throw much light upon the fundamental principles of that science and to suggest important questions as to the relation of mathematical analysis to ordinary languages. The method has been applied to test the "systems of affinity and consanguinity" of Dr. Morgan of Rochester, New York.

On a Microscope with Arrangements for Illuminating the Sub-Stage, by E. Crossley.—The author stated that, using a bullseye condenser, the light from the lamp is thrown into the hollow horizontal axis of the microscope, and by means of a prism placed in the centre of this axis is reflected forwards in the direction of the axis on which the swinging sub-stage turns. The arm of a swinging sub-stage is made in the form of a box, and carries a second prism on the axis, on which it moves so as to intercept the rays of light coming from the first prism, and reflect them in the direction of the arm or box. At the end of the box is a third prism, which throws the rays of light forward on to the mirror, by means of which they are finally directed to the object on the stage. No change in the position of the microscope on its horizontal axis affects the direction of the light from the lamp, and whatever the position of the swinging sub-stage, whether above or below the stage, the illumination remains constant upon the object. The greatest facility is thus given for illuminating the object at any angle, and also seeing which is most suitable. The prisms used are one-inch, and give sufficient light for a one sixteenth-inch object-glass with a Ross B-eyepiece, a suitable condenser being used beneath the stage.

Observations of Atmospheric Electricity at Kew Observatory during 1880, by G. M. Whipple.—The author having spoken about the work already done, stated that he had devised a modification of Prof. Everett's method, and had constructed a glass scale by means of which curves could be tabulated with great facility. They had commenced tabulating and discussing the accumulated records, and he was able to state some of the facts derived from the curves for 1880. Having determined the atmospheric tension for every hour during the year when measurement of the trace was possible, the diurnal, monthly, and annual variations were computed. The months of maximum tension were January and March, and of minimum tension August and September. From the year's observations it was found that the laws vary in summer and winter; for the summer months the tension was greatest with an east wind and lowest with a north wind, whilst in winter the tension was greatest with north and north-west winds and least with south-east winds. From the results obtained it was found that light winds had a higher potential than strong winds. This, however, was not well marked in summer, but is almost entirely due to winter observations.

On Prof. Phillips' Rainfall Observations made upon York Minster, by G. J. Symons, F.R.S.—The author, referring to the experiments established at York Minster, said that three gauges nearly identical in pattern were placed, one in the museum garden, one on the roof of the museum, and the third on a pole about 9 feet high placed on the centre tower of York Minster. These gauges were measured at various but identical times during the years 1832-1835, and the results were :—

	Total rain.	Ratio.
Museum garden 2 inches above ground ...	21 81 ...	100
Museum roof 44 feet ,, ...	17·39 ...	80
Minster tower 213 feet ,, ...	12·99 ...	60

Prof. Phillips stated the real amount of the diminution of rain at the upper stations depended upon the temperature of the seasons; the diminution did not vary uniformly as the square root of height, being in winter only as the cube root. Prof. Phillips' experiments soon became known, and Prof. Bache of Philadelphia set up four gauges at the angles of a square tower 162 feet high. His experiments were reported to the British Association in 1838. In 1861 Mr. Stanley Jevons made an important theoretical contribution to this investigation; he pointed out the weakness of the different extant theories, and showed that the phenomena observed were all consistent with the theory that the fall of rain was practically identical at all elevations, and that the observed differences were due to the imperfect collection by the gauges; he also stated that towers, buildings, and even the gauge itself, were obstacles to the rain-bearing current of air, and he concluded that less rain would fall on the summit of the obstacle than elsewhere, the surplus being carried forward to the lee side. Similar observations have been made during the last fifteen years, which have also been supplemented by anemometric observations, and these have proved that the difference in the amount collected was always greatest when the wind was strongest. The subject of late has been investigated by Mr. Dines, who placed several gauges 50 feet from the ground on the tower of his house. In 1877 Mr. Dines read a paper, and said that there was no actual decrease at the higher level, but a diminished collection due to eddy; he added that he found a large gauge on the tower caught much more than a small one. Mr. Rogers Field now took the matter up, and setting down the values so as to form curves he showed :—1. That the ratio of the rainfall on the tower to the rainfall on the ground depends on the force and direction of the wind. 2. That when there is no wind the rainfall on the tower is about the same as the rainfall on the ground. 3. That when there is wind the amount of rain falling on the tower will vary on different portions of the tower, the portion nearest the point at which the wind strikes the tower receiving less rain than falls on the ground, and the portion farthest from the point at which the wind strikes the tower receiving the same or more rain than falls on the ground. 4. That the excess of rain falling on the portion of the tower farthest from where the wind strikes will, to a large extent, compensate the deficiency of rain on the portion nearest to where the wind strikes, but whether to a sufficient extent to make the average amount of rain falling on the tower equal to that falling on the ground cannot be determined from these experiments. From these conclusions it is clear that if the building be flat and large, the fall in the middle of the roof ought to be nearly the same as on the ground, and in two instances this is so, first at Messrs. Marshall's factory at Leeds, and secondly Mr. Dines on a roof of 5000 square feet of area. Thus finally experimental evidence has corroborated the views of Mr. Stanley Jevons, given above.

On some of Bell and Tainter's Recent Researches and their Consequences, by W. Lant Carpenter.—The author referred to the researches of Messrs. Graham Bell and Tainter upon the sonorousness of matter under the influence of a beam of intermittent light, and described the receivers employed, in which substances are placed for examination. Porous substances gave louder sounds than dense ones, and those of a dark colour louder than light when a rapidly intermittent beam fell on them. An apparatus had been contrived by Mr. Tainter for measuring the relative sonorous powers of bodies, which was described by the author. He also stated that it had occurred to him that a modification of this apparatus might be employed for audibly estimating the relative intensities of two lights when intermittent beams fell from them upon two precisely similar receivers. The author proposed to call this instrument an audible photometer, and said that some rough experiments had somewhat justified his expectations.

On Magnetic Disturbances, by Prof. W. G. Adams, F.R.S.—The author, in considering magnetic disturbances, stated that certain facts about them had long been known; from the observations of Gauss in 1834 the disturbing power was found to increase in northern latitudes; it was also found that the appearance of a disturbance occurred in several places at the same instant, but with great differences of results. The force seemed to originate at a certain point in the interior of the earth, and the direction of the disturbing force seemed constant, yet great differences were observable at places not remote from one another. Sabine found that these disturbances had daily and yearly variations from their mean values, and that they have an eleven-year period corresponding to the appearance of spots upon the sun. It has been shown by observations that magnetic disturbances and electric currents on the earth are related; these electric currents in the earth have commonly been attributed to changes of temperature. The month of March, 1879, was chosen for a comparison of the photographic records of magnetic disturbances, and records for the whole month were sent from Lisbon, Coimbra, Stonyhurst, Vienna, St. Petersburg, and Bombay in the northern hemisphere, and from Melbourne and the Mauritius in the southern hemisphere. Taking the disturbances on March 15-16, 1879, as an instance, we see that soon after 10 a.m. Greenwich time on the 15th, a disturbance-wave happens, which shows first a diminution and then an increase of horizontal force at St. Petersburg, Vienna, Kew, and Lisbon, and also at Melbourne in Australia. At 9.30 p.m. of the same day a magnetic storm begins, and continues for about an hour. It is felt in the northern and southern hemispheres. At all stations in Europe the horizontal force is increased in the first part of the storm, and then diminished. At Lisbon the vertical force is first increased and then diminished, and at St. Petersburg and Stonyhurst there is a diminution in the vertical force at the same time as at Lisbon. Regarding the declination needles, we find that at St. Petersburg, Melbourne, and Bombay the declination westward is first increased and then diminished, whereas at Kew and Lisbon the motions are in opposite directions. At Bombay and Mauritius, near to, but on opposite sides of, the equator, the declination needles are deflected opposite ways. If we assume that by magnetic induction the earth's magnetism is altered, the position of the magnet which would cause the disturbance must be such that its pole, which attracts the marked end of our needle, must lie at the beginning of the disturbance to the east of Kew and Lisbon, to the north of Vienna, and to the north-west of St. Petersburg; the Lisbon vertical force curve also shows it to be below the surface of the earth. Hence an inductive action equivalent to a change of position of the north magnetic pole towards the geographical pole would account for these changes. The strengthening and weakening of a magnet with its north pole to the north on the meridian of Vienna might account for magnetic changes observed between 9.30 and 10.30 at night, Greenwich time, on March 15, 1879. In attempting to explain this disturbance by currents of electricity or discharges of statical electricity in the air above the needles, we must imagine that at first there is a strong current from the south-west over St. Petersburg, from the west over Vienna, and from the north-west over Kew and Lisbon, the vertical force needle at Lisbon showing that the current from the north-west lies somewhat to the east of Lisbon; that at the Mauritius this current is from the north, and at Bombay from the south. Thus we must imagine that a current of electricity passes down from the north-west to the south-east, going on towards the east over Vienna, and towards the north-east over St. Petersburg. This must be kept up very much along the same line throughout the first part of the disturbance, and then the current must be altered in strength in the same manner at all stations. An examination of the principal disturbances at Kew and at St. Petersburg seems to show that (1) a diminution in the horizontal force is accompanied by greater easterly deflections of the declination needle at St. Petersburg than at Kew; (2) increase of horizontal force is accompanied by greater westerly deflections at St. Petersburg than at Kew, or is sometimes accompanied by a westerly deflection at St. Petersburg and an easterly deflection at Kew. Only moderate disturbances have already been considered, and the author now treats of a much larger magnetic storm which began at 10.20 a.m. Greenwich time on August 14. This storm may be divided into three storms: one lasting from 10.20 on the 14th to 1 a.m. on the 15th; a second from 11.30 a.m. on the 15th to 7.30 a.m. on the 13th; and the third from 11.50 a.m. on the 13th to 7 to 8 a.m. on the 14th of August. The first storm begins at [illegible] at the same instant at all stations. There is a [illegible] especially in the horizontal force curves, throughout [illegible] part of this storm, and certain points in it stand out [illegible] The deflections are alike at Lisbon, Kew, Vienna, [illegible] burg, and after the first very sudden deflection at [illegible] The greatest effect is produced at St. Petersburg; [illegible] between the large disturbances at Vienna and [illegible] Canada, places differing about six and a half hours [illegible] remarkable. About 11.45 p.m. and 2.40 p.m. there are [illegible] remarkable points of agreement. From about 2 p.m. [illegible] p.m. Greenwich time, *i.e.* from about (1 a.m. to 8.5 [illegible] Toronto time, the deflections are opposed at Toronto [illegible] Vienna or Kew. This would point rather to solar [illegible] cause of the disturbance. At 9 p.m. the disturbance [illegible] the same direction, but about 11 p.m., which St. Peters[illegible] agrees in direction with the others in a very [illegible] storm, at Toronto the direction of the deflection [illegible] and this reversal of curves continues until about the [illegible] first of the three storms. The second storm, the most [illegible] able of the three, began about 11.30 a.m. on the [illegible] lasted until the next morning. At Toronto the line [illegible] edge of the paper on which the photographic record [illegible] At Vienna and Melbourne the motion is so rapid that [illegible] is not sensitive enough to receive the impressions. At [illegible] midday, the time of greatest disturbance at Lisbon and [illegible] Wei near Shanghai in China, two places nine hours [illegible] and nearly in the same latitude, the vertical force [illegible] precisely the same fashion. At St. Petersburg the [illegible] horizontal force was one thirty-fifth part of the whole [illegible] tal force, and the total force was changed to about [illegible] part of its full value. These magnetic changes are so [illegible] to be quite comparable, as we see, with the earth's [illegible] so that any cause which is shown to be incompetent [illegible] nature of things to produce the one can hardly be [illegible] account for the other.

The number of mathematicians who attended the [illegible] very remarkable, and among the foreigners present may be [illegible] tioned Messrs. Halphen, Chemin, Rudolf Sturm, [illegible] Stephanos, and W. Woolsey Johnson (Annapolis, U.S.). [illegible] separate mathematical department was formed, which [illegible] three days, and more than thirty papers on pure mathematical subjects were read, many of them being of great interest. [illegible] Halphen made a communication on Steiner's theorem [illegible] the positions of the centres of conics passing through [illegible] points, and gave an elegant extension of the theorem to [illegible] guish the cases in which the three points lay on the [illegible] opposite branches of the curve. He also made [illegible] on the subject of linear differential equations and hypergeometrical series; and in a fourth paper he considered the [illegible] aspects in which points in a plane may be viewed. He [illegible] that two points may be thus viewed in six ways, that [illegible] can be viewed in nine ways, and illustrated this by a [illegible] and extended the theorem to five points. Prof. Sturm communicated an elaborate memoir on curves of double curvature, relating to the researches of Cayley and Halphen, which was ordered to be printed *in extenso* among the reports. [illegible] phanes read several papers, in one of which he showed that the different homographies which exist upon a straight line, which are triply infinite in number, may be [illegible] points of space. A simple and beautiful [illegible] particulars of these systems was thus obtained.

The other papers included communications by [illegible] *On the Transformation of Elliptic Functions*, and [illegible] *Theorem*; by Prof. H. J. S. Smith, *On the Differential [illegible] tions satisfied by the Modular Equations, and on the Form of the Multiplier in the Transformation of Elliptic Functions*; by Mr. J. W. L. Glaisher, *On the q-Series in Elliptic Functions*; by Dr. Hirst, *On Consequences of the Second Order and [illegible] Class*; and by Prof. R. S. Ball, *On the Application of [illegible] Euclidian Space to a Problem in Kinematics, and an Extension of the Theory of Screws to the Dynamics of any [illegible] System.*

SECTION B—CHEMICAL SCIENCE

The Present State of Chemical Nomenclature, by [illegible] Williamson, Ph.D., F.R.S.—The author stated that perhaps few departments of science in which [illegible] had been adopted, and to a great extent [illegible]

Digitized by Google

formation of names, as in their own science of chemistry. The practice of stating in a name as briefly as possible certain facts, and as a rule important facts, had been, as every chemist knew, the chief object of their nomenclature. But he thought he might be permitted to say that if one looked to the composition of any result like the present nomenclature of chemistry—which had been guided by intellectual principles—it was of immense importance to consider its purely intellectual principles, viz., the principles of convenience, and perhaps even of popular tastes, and, if he might be allowed to imagine such a thing, even the prejudices which occasionally arose among a great number of men who adopted any particular form of expression. He proposed to refer to the question from the different points of view. If they had occasion to consider, without knowing anything about it, what was the most important condition to which every name ought to conform, he fancied there would be no two opinions on the matter. The first and most important condition and requirement of every name of a thing that was important was that it should call to the minds of those who used it, without ambiguity, some one particular thing or one particular idea. He should be inclined to consider a code of laws by which their action would be rendered uniform with regard to names, and which would establish such fundamental principles that an absence of ambiguity would be secured. The more any name could be defined and shortened the better it would be for chemistry. In the modern progress of chemistry, especially in that department of which the growth had been enormously great—he meant the many carbon compounds—the purpose of obtaining clearness and avoiding ambiguity in the nomenclature had been, with few exceptions, satisfactorily attained. But he thought members would agree with him that in the names given to some compounds more complex than others the chief object of convenience had not been attained to an equal extent. They found names given which, when carefully considered by chemists, told a story, but a very long story, and in a manner which was really free from ambiguity, but only by aid of a great number of syllables, and a compound word of inconvenient length was this attained. On the other hand, amongst very common substances that systematic process had been, he thought, to a considerably less degree adopted. The older names of commoner substances, such as salts, were to a great extent based upon facts which were true, but were by no means the only facts to be recalled. Of course every chemist knew the great number of names that were in common use, and how far they served to recall a particular process, but only one among many processes by which the substance could be formed. On the other hand, many names had grown up from bodies which were purely empirical—names which did not recall any particular properties, but served with great convenience and without ambiguity to indicate the body. If they looked to the circumstances which affected that one condition which he had submitted as essential to names being perfectly free from ambiguity, there was perhaps hardly one condition more practically important than this, that there should be in the names as little change as possible, and more especially was this the case when a name that had once been given had come to be used in relation to particular substances. It was within the memory of chemists that changes of name had taken place not only when a particular substance was recalled, but there were also a considerable number of cases showing that the name given at one time to one body was afterwards given to another. The circumstances attending such changes were in some instances of an exceedingly reasonable kind, and well worthy of consideration after it was found that there were grounds for believing that the names belonged more properly to other substances. If, however, changes introduced confusion, they were necessarily injurious to the progress of the science. When he looked back to the successive steps by which their knowledge had risen to its present position, and to the ideas that had succeeded one another, he felt that in order to really understand chemistry, and to be able to arrange the facts in a convenient order, they must see how they had grown up. If that was important in practical matters, it was even more important in what he might call the scientific work. He ventured to think, at all events he had always felt, that to use with safety any idea that they were accustomed to use, it was almost essential, and was certainly of importance, that they should endeavour to trace the origin and growth of that idea, so as to see what it really meant. His object in bringing the subject before the Section was to obtain from his colleagues and friends their views on the present state of matters, and to give them the opportunity of considering together—those who more especially felt it their duty to contribute by any means in their power to the advancement of science either in guiding the operations or growth of those names—whether there could not be greater concert among chemists as to what was being and what had been done, so that they might conform their doings to certain laws. He had frequently seen with regret some features in chemical nomenclature that had been springing up of late years. He had seen some habits gaining ground which appeared to be at variance with the best principles of nomenclature—he would assume such to be the case. But there were laws in the growth of those words, and he could not doubt for his own part that if chemists came to recognise those laws, or rid themselves of them, the future growth of words would gradually come to be a more systematic guide. It had sometimes been felt that to attempt to solve the problem would be useless, and that irregularities had become so prevalent that it would be hopeless to think they could ever remedy them. But he thought differently, and would urge that in the direction he had pointed out they were only now beginning to move. There was only one convenient division among names. That division, of course, was not absolute, because no such division could be absolute; but the great majority of names were used to denote things and ideas. Some names were of little use in relation to the particular ideas, and therefore it seemed to him that the best way to obtain a name was as the result of experiment. If founded on that principle there could be no ambiguity. At the present time, as their views had considerably changed, and as they had not attained finality in their operations, there was much to be learnt, and it was reasonable to suppose that if they adopted a particular name to indicate a particular thing it might perhaps turn out at some time hence an error upon which people would look back as historical. With regard to names, especially theories, there were some of them that had certainly served important purposes. It was then really essential to the arrangement of their ideas that they should for the time imagine something to exist, and that they should recall by some convenient name that which they assumed or imagined. Names, in his opinion, ought to express ideas; but there were many names introduced which he thought were used for no better purpose than to express the absence of ideas. It often happened that when exploring any particular part of a field, they got a rational clue which led them clearly and well for a certain way; and they failed to follow it further. The cases were numberless, but one of the most important was that of chemical combination itself. Complex bodies were far more numerous than the few simple bodies with which they had to do, and while in the habit of using the term chemical combination, they had concealed their ignorance of the state of combination. Others used the term molecular combination, and there again they concealed their ignorance of the bodies to which it was applied. Among the present anomalies in names there was one which he ventured to submit to the consideration of the Section, and which had grown up to some extent of late, and that was the replacing of empirical names of things by names, which, while he would call them rational, because they served to recall intelligibly and without ambiguity, served to recall the number of atoms. He mentioned such cases by way of illustrating the practice which had seemed to him to be gaining ground of late years, for the purpose, as some said, of increasing the clearness of statement. He had no doubt that the words were framed for the purpose of conveying to the mind something useful to know, and as names formed on that principle had been found to be based on those superseded by others, he thought when they came to such names as indicated molecular composition it was better to avoid them, because, as he had said, they had not arrived at finality. The chemists of fifty years ago were as confident as chemists of the present day in the matter of nomenclature; and therefore the more they could obtain names without ambiguity and without liability to change in the future, the more probable was it that such names would stand and continue to be used. A crowd of material presented itself just then to his mind, but he did not think it would be well to trouble the Section with further remarks. He merely wished to throw out the ball for his colleagues to deal with.

Cellulose and Coal, by C. F. Cross, B.Sc., and E. J. Bevan.—This is a continuation of the authors' researches on bast fibre (Chem. Soc. *Journ.*, 1880, abstr. 666). By the action of sulphuric acid (sp. gr. 1·65), at 70°, on jute fibre, an insoluble, black, spongy substance has been obtained; that the cellulose

Digitized by Google

of the fibre contributes to the formation of the substance, is shown by the formation of a similar compound from pure cellulose and dextrin. A chlorinated product ($C_{30}H_{16}Cl_4O_{10}$) has been obtained from this black substance, its properties are similar to those of the aromatic substance described in a previous paper (*loc. cit.*). The production of this spongy substance is usually a destructive one, and attended with an evolution of CO_2 and the production of acetic acid, &c. It is not, however, necessarily so, for when the action of the sulphuric acid is arrested before the evolution of carbonic dioxide, a reddish brown solution is obtained, from which when poured into water a copious flocculent precipitate is obtained, of a body very similar in chemical properties to the black substance described above. The chlorine substitution products are easily converted into astringent bodies, producing dark-coloured precipitates with iron salts and copious coagulation with gelatine. These facts, together with the following :—(*a*) Meissner and Shepard's conclusion that the hippuric acid of herbivorous urine is derived from an aromatic body present in the fodder, apparently a form of cellulose, which the authors have identified as similar to the characteristic consitituent of bast fibre; (*b*) the previous demonstration by the authors of the homogeneous nature of jute fibre, and that in its resolution the percentage yield of cellulose may be increased apparently at the expense of the aromatic constituent; (*c*) that the process of liquification (or the formation of tannin-like substances) is said by microscopists to be due to an intrinsic modification of the substances of the cell-walls, *i.e.*, of the cellulose, and not to an infiltration of the substances present in the cell cavity; (*d*) the numerous cases in which tannic acid is formed at the expense of plant structures of the nature of cellulose—lead the authors to conclude that, until the contrary is proved, lignin must be regarded as derived from cellulose by chemical modification. The spongy black substance, previously described, dries to a hard mass resembling cannel coal, with which the authors have compared it, and have obtained similar products of chlorination and nitration, and further support of the opinion that coal is not carbonaceous in any more special sense than alcohol, but is rather, as supposed by Balzer, composed of C, O, H, N bodies, which are genetically, if not homologously related. The authors suggest that cellulose, lignite, peat, lignin, and anthracite are terms of an infinite series differentiated under the conditions of their formation.

Hydration of Salts and Acids, by C. F. Cross, B.Sc.—The method adopted by the author for investigating the rate of hydration of a substance consisted in exposing about 1 gramme of the substance in a bell-jar of 2000 c.c. capacity, to an atmosphere saturated with aqueous vapour. After a critical investigation of the probable errors, the "Jolly" Federwaage was used to make the numerous weighings required, and thus the method of observation was rendered very expeditious. The paper contains diagrams representing the velocities of hydration for certain salts and oxides. The author has observed that, under these "artificial" conditions of exposure, all the soluble salts examined deliquesce. This takes place in some cases without previous hydration, *e.g.*, with potassium bichromate, and in such cases the water may be removed by pressure between blotting paper. In other cases, *e.g.*, with $CuSO_4$, the salt deliquesces after uniting with water of chemical hydration, and in a different manner. It would therefore appear that the continuity of the phenomena of hydration and solution, as regards the determining cause, is demonstrated by these observations.

On Colliery Explosions, by W. Galloway.—The author gave an account of his experiments made to show the influence of coal-dust in colliery explosions. In July, 1878, he made three sets of experiments with different kinds of apparatus. In the first set, in which coal-gas was used instead of fire-damp, and the gas and air were carefully measured, and then coal-dust added, it was shown that 2 per cent. of gas, mixed with air, was rendered inflammable when coal-dust was added; 3 per cent. of gas made this mixture slightly explosive; 4 per cent. made it still more explosive; and 5 per cent. produced a violent explosion. The total quantity of gas and air mixture was little more than a cubic foot. In the second set it was shown that the return air of a mine containing 2 per cent. of fire-damp became inflammable when coal-dust was added to it. In the third set the explosion of a mixture of air and fire-damp was made to raise and ignite coal-dust scattered along the floor of an artificial gallery 70 or 80 feet long, and 14 inches square inside. The flame of the fire-damp explosion alone was found to be 7 feet or 8 feet long; the flame of coal-dust in pure air was 35 feet x 40 feet long; and the flame of coal-dust in the return air employed in the first set of experiments was 80 or 90 feet long. The publication of these results called further attention to the subject, and after the Seaham explosion the Home Secretary requested Dr. Abel to inquire, amongst other things, into the influence of coal-dust in promoting that disaster. Prof. Abel made experiments near Wigan, and obtained results similar in kind to the author's, but different in some respects. In July the present year the author made experiments with apparatus of the following description: A sheet-iron cylinder 6 feet long by 2 feet in diameter, closed at one end and open at the other, had its open end bolted to a wooden gallery 126 feet long by 2 feet square inside. One end of the wooden gallery was thus closed by the sheet iron cylinder, an explosion chamber, and the other end was open. Six sheets of newspaper were placed between this open end of the explosion chamber and this gallery, and a tight joint was ensured by means of screws. Rather less than 2 cubic feet of fire-damp was carefully measured and introduced into the explosion chamber. The wooden gallery contained only pure air. The air and fire-damp contained in the explosion chamber was thoroughly mixed by means of an appropriate mechanical arrangement, and the mixture was exploded. The explosion burst the sheets of paper, and the resulting flame travelled about 12 feet or 14 feet along the gallery, and as suddenly disappeared. The gallery was then strewed with a layer of the coal-dust from ¼ inch to ½ inch thick along its floor, and some was placed on shelves which stood in sets of three, one above the other, at distances of 10 feet from each other, along the gallery. The same arrangement as before was then made in regard to preparing for a fire-damp explosion, exactly the same quantity of fire-damp being measured, mixed, and exploded. By this explosion of the fire-damp mixture the coal-dust was raised in a cloud throughout the whole length of the gallery, part of it was projected out into the air to a distance of 20 feet or 30 feet beyond the end, and, after the lapse of an appreciable interval of time, the flame found its way to the end of the gallery and flashed out through the cloud of dust to a greater or less distance according to circumstances. The greatest length of flame thus obtained with coal-dust and pure air was 147 feet on one occasion, and from 100 feet to 140 feet very often. He considered that these results proved in the most convincing manner that coal-dust formed an inflammable mixture with pure air, and they settled once for all the question as to how an explosion in one district of a dry and dusty mine could penetrate to the most distant parts of every other district of the workings in the same mine. In conclusion the author spoke of the necessity of keeping the floors of mines damp, and thus lessening the dangerous influence of coal-dust.

SECTION C—GEOLOGY

A preliminary Account of the Working of Dowkerbottom Cave in Craven during August, 1881, by E. B. Poulton, M.A. F.G.S.—Dowkerbottom Cave is 1250 feet above the sea, between Arncliffe and Kilnsey. Its mouth is merely a fall in the roof of the cave, which stretches from either end of the fissure thus formed. The original mouth is not now visible, but is probably to be found at the foot of a slope to the south. During most of its course the chambers and passages of the cave are not separated by any great thickness of rock from the ground above, and thus other falls must be expected to occur. The eastern division of the cave is about 450 feet long, and has three fine chambers separated by two passages, the first very short, and the second very long. This division ends under high ground, and the true mouth must be in the other, or western cave. The last chamber is characterised by mechanical deposits—blocks of limestone fallen from the roof and a stiff brown clay beneath. In the other chambers and passages are chemical deposits—hard and soft stalagmite. The western division is smaller, but also contains three chambers and two passages. It must be about 250 feet long. Chemical deposits, with some falls from the roof, are present throughout. In former workings by Mr. Farrer, Mr. Denny, and Mr. Jackson, the first chambers were explored in their surface layers at least, and here were found the numerous metal and bone ornaments and implements, together with the bones of animals usually found in the historic layers (of Roman-British age) in caves. The second passages have also been worked, and part of the second chamber on the eastern side. Other parts of the cave appear to be quite untouched. The great

Digitized by Google

difficulty in working the cave is the removal of the *débris* to prevent its interfering with further work. We therefore put up a windlass over the eastern entrance and cleared a way for barrows through the talus below. Beneath the talus the black earth, in which remains had been previously found, was seen, and many articles of Roman age were taken from it. Chamber III. was marked into parallels, and these into squares. In the centre we sank a shaft and passed through the following layers:—(1) *Romano-British layer*, a black earth with pottery, ornaments, &c., and numerous bones, usually from 1 to 2 inches thick; (2) *hardish stalagmite*, about 6 inches thick, in one place containing the bones of a dog or small wolf; (3) *soft stalagmite* 4 inches thick; (4) *hardish stalagmite* 6 inches thick; (5) *soft stalagmite* 2 feet 6 inches thick; (6) *stiff brown clay* with large angular blocks of limestone fallen from the roof firmly imbedded in it. This layer was 8 feet deep, as far as we saw it. The last two feet are laminated and contain smaller blocks. At the depth of about 12 feet from the surface we came upon part of the solid limestone floor or side of the cave, sloping steeply downwards. There were no indications of a change in the nature of the deposit at the junction with the limestone, and the clay appears to extend much deeper than the level at present reached. Thus below the stalagmite purely mechanical deposits succeed, and no limestone blocks are found above this horizon, although the stalagmite has been removed over a large part of the floor of the chamber. No traces of a fauna have been as yet found below the first hardish stalagmite; indeed all the deposits passed through below the stalagmite indicate the former presence of a still lake in which the great thickness of clay slowly accumulated. Further work was stopped by the heavy rain which flooded the shaft dug in the clay. It is interesting to note that the former condition of Chamber II. is identical with the present state of the third chamber in the preponderance of mechanical over chemical deposits. The change from mechanical to chemical deposits was probably produced by a change from accumulation in still water to accumulation in running water. Possibly also the absence of blocks fallen from the roof in the stalagmite may be due to the bicarbonate of lime contained in the water which percolated through the roof, cementing together the limestone blocks. The absence of this cement when the clay was deposited may be due to the absence of solvent power in the water which then percolated through the roof. For the carbon dioxide would not be evolved from a soil deficient in organic matter, as the soil covering the Yorkshire hills for a period long after the Glacial period must have been. The author expresses his best thanks to Mr. J. R. Tennant of Kildwick Hall, Leeds, and to Mr. J. R. Eddy of Carleton, Skipton, who gave, on behalf of the Duke of Devonshire, the permission to work the cave, and further aided with kind help and advice all through the work.

On Asteromilia Readi, a New Species of Coral from the Oligocene of Brockenhurst, by Prof. P. Martin Duncan, F.R.S.—The author described the characters of this coral, placing it in the genera established to include certain corals from the West Indies, and some dredged up in the Carribean Sea by Count Pourtalès. He referred to the genus Madrepora, which lives in twenty to twenty-five fathoms, 74° Fahr. temperature, reef-building coral, or on banks in a turbulent sea. The specimens are generally rolled, but some are absolutely perfect, and clearly give the history of the physical conditions of the close of the Eocene period in the south of England, which then resembled the climate of the Bermudas.

On the Formation of Coal, by E. Wethered, F.G.S., F.C.S.—The author considers (1) that coal was not formed from vegetation of the Lepidodendroid type, and that therefore the Stigmaria found in the underclays are not the roots of the vegetation which gave rise to the coal; (2) that the varieties of coal and the change which sometimes takes place in one and the same seam are not due to metamorphism, nor are they dependent upon the contorted state of the surrounding strata, but arise from the greater or less chemical decomposition of the vegetable mass, influenced by the circumstances under which it was submerged. On the land grew the vegetation of the period, represented by the Lepidodendrons, Sigillaria, Calamites, &c. As the land sank and the waters encroached, the land vegetation was gradually washed away, but the roots remained in many cases, and those which offered the greatest resistance to decay are the ones preserved in a fossil state—hence the occurrence of Stigmaria. As the waters advanced the ground would become swampy, and then we might expect to see spring up reeds, mosses, and other vegetation suitable to the changed condition; it is to vegetation of this kind that the author ascribes the formation of coal. With a view of ascertaining whether the chemical composition of the beds which overlie a seam of coal which has changed from bituminous to anthracite also changed, the Welsh "nine-feet" seam was selected, which near Cardiff is semi-bituminous, and at Aberdare becomes anthracite. Specimens of the overlying strata were selected from the two districts at each foot above the coal for five feet; these were analysed, and it was found that the beds from near Cardiff were considerably more argillaceous and, as a whole, less ferruginous than those at Aberdare.

On the Palæozoic Rocks of North Devon and West Somerset, by W. A. E. Ussher, F.G.S., Geological Survey of England and Wales.—The classification adopted is as follows:—

LOWER DEVONIAN	FORELAND GRITS	Red and purplish grits, fine-grained, and in places siliceous.
	LYNTON BEDS	Grey, even-bedded, and jointed grits, grey schists, and schistose grits with films of calcareous matter.
MIDDLE DEVONIAN	HANGMAN GRITS	Coarse white quartzose, red-speckled grit, in and upon red and grey rather fine-grained grits associated with shaly and slaty beds.
	ILFRACOMBE SLATES PASSING INTO MORTE SLATES	Grey and silvery slates and shales with arenaceous films, and impersistent bands of limestone passing into pale greenish unfossiliferous quartzose slates.
UPPER DEVONIAN	PICKWELL DOWN BEDS	Indian-red slates upon red, green, and grey grits, with local purple slate basement-beds passing into the Morte slates.
	BAGGY BEDS	Green slates with *Lingula*; brown micaceous grits with *Cucullæa*, positions of these horizons apparently reversed near Wiveliscombe.
	PILTON BEDS	Bluish and greenish grey argillaceous slates, with occasional thin films of limestone and masses of grit (as at Braunton, &c.).

The Foreland Grits occupy an area (superficial) of thirty square miles, extending from Countesbury to Dunster. The Hangman Grits form the range which includes Dunkery Beacon, also the whole northern part of the Quantocks. Their relations to the Ilfracombe Slates are much complicated by faults around Croydon Hill and on the Quantocks; and the prevalence of grits in the Ilfracombe series, whilst indicative of lithological assimilation, makes the boundary rather indefinite.

On the Characters of the "Lansdown Encrinite" (*Millericrinus Pratii*, Gray, sp.), by P. Herbert Carpenter, M.A.—The "Lansdown Encrinite" is a species of *Millericrinus* (*M. Pratii*, Gray, sp. = *Apiocrinus obconicus*, Goldfuss) from the Great Oolite on the top of Lansdown, near Bath. It is remarkable for the very great variation in the characters of its stem and calyx. The former may reach 50 mm. in length, and consist of seventy discoidal joints; or there may be less than ten joints, the lowest of which is rounded off below, and its central canal closed up. Various intermediate conditions may occur between these two extremes, while in some specimens there may be only two to four stem-joints; and in one case the whole stem is represented by a slightly convex imperforate plate on which the basels rest. This specimen, taken by itself, would be naturally regarded as a *Comatula* of advanced age, in which the cirrhus-sockets had disappeared from the centre dorsal just as they do in the recent *Actinometra Jukesii*. The general appearance of the calyx is very similar to that of *Pentacrinus Wyville-Thomsoni* from the North Atlantic. But it is remarkable for the number of small intercalated pieces which it may contain. The basels are frequently separated from one another, or from the radials, by minute plates which, while regularly developed all round the calyx in some specimens, are entirely absent in others. The nearest allies of *M. Pratii* seem to be *M. Munsterianus*, var.

Digitized by Google

Buchiana and *M. Nodotianus*. It stands on the extreme limit of the genus, connecting it with *Pentacrinus* on the one hand, and with the free *Comatulida* on the other. It is thus a synthetic type, as would naturally be expected from its geological position; for it is probably the earliest known species of the genus, except perhaps for two doubtful Liassic forms, which are known only by isolated plates and stem-joints.

Observations on the two Types of Cambrian Beds of the British Isles (the Caledonian and Hibernо-Cambrian), and the Conditions under which they were respectively Deposited, by Prof. Edward Hull, LL.D., F.R.S.—In this paper the author pointed out the distinctions in mineral character between the Cambrian beds of the North-West Highlands of Scotland, and their assumed representative in the east of Ireland and North Wales. In the former case, which included the beds belonging to the "Caledonian type," the formation consists of red or purple sandstones and conglomerates; in the latter, which included the beds belonging to the "Hibernо-Cambrian type," the formation consists of hard green and purple grits and slates, contrasting strongly with the former in structure and appearance. These differences, the author considered, were due to deposition in distinct basins, lying on either side of an archæan ridge of crystalline rocks, which ranged probably from Scandinavia through the central Highlands of Scotland, and included the north and west of Ireland, with the counties of Donegal, Derry, Mayo, Sligo, and Galway, in all of which the Cambrian beds were absent, so that the Lower Silurian repose directly and unconformably on the crystalline rocks of Laurentian age. As additional evidence of the existence of this old ridge, the author showed that when the Lower Silurian beds were in course of formation the archæan floor along the west of Scotland must have sloped upwards towards the east, but he agreed with Prof. Ramsay that the crystalline rocks of the Outer Hebrides formed the western limit of the Cambrian area of deposition, and that the basin was in the form of an inland lake. On the other hand, looking at the fossil evidence both of the Irish and Welsh Cambrian beds, he was of opinion that the beds of this basin were in the main, if not altogether, of marine origin, and that the basin itself had a greatly wider range eastward and southward, the old archæan ridge of the British Isles forming but a small portion of the original margin.

On a Discovery of Fossil Fishes in the New Red Sandstone of Nottingham, by E. Wilson, F.G.S.—The author called the attention of the Section to a recent discovery of fossil fishes in the Lower Keuper Sandstone of England—a circumstance of sufficient rarity in itself, apart from any palæontological results, to deserve at least a passing notice. During the construction of the Leen Valley Outfall Sewer in 1878, a remarkably interesting section was given by the tunnelling driven through Rough Hill, or Colwick Wood, near Nottingham, showing the lower beds of the waterstones resting on a denuded surface of the "Basement Beds" of the Keuper. The lowest stratum of the waterstone was a sandstone about a foot thick, with streaks of red and green marl, and a seam of pebbles at the base. The fishes occurred in this bed, and chiefly in a thin seam of red marl overlying the pebbly seam at the very bottom of the Waterstones; they were present in large numbers, as if in a shoal, for a distance, in the line of section, of about thirty-three feet. The specimens obtained have been examined by several competent authorities, but unfortunately their state of preservation is so bad that nothing certain can be made out as to their precise zoological affinities. Dr. Traquair, however, believes that they probably belong to some species, new or old, of the genus *Semionotus*.

Glacial Sections at York, and their Relation to the later Deposits, by J. Edmund Clark, B.A., B.Sc., F.G.S.—The York area chiefly consists of glacial beds, which form the high ground and various extensive low tracts more or less remote from the Ouse. Glacial depressions have been filled up with brick-earths, and, in exceptional cases, peat-beds. Where the river channel is narrowed below the city, the crests of the banks are capped with gravels. The peat-beds of Campleshon Pond and part of St. Paul's Square rest on the levels covered with brick-earth. Near Ouse Bridge a peat-bed 50 feet down, at Bratt's Brewery, has been called interglacial; but the beds above it cannot positively be asserted to be glacial; for at the waterworks similar beds appear, in which plant-roots were detected 20 feet down. The following sequence of the beds can be established:—

Brick-earths.—At the Harrogate Signals, a quarter of a mile further north, the junction of the upper beds with glacial (or probably glacial) beds is seen. At a low place [illegible] boulder clay protrude even here through the upper [illegible] elsewhere depressions are filled with brick-clays, [illegible] worked.

Gravels.—The gravel beds at Fulford and [illegible] side of the Ouse are much alike. The beds are roughly stratified, with boulders of a quarter-ton [illegible] stones are precisely the same as those in the boulder-[illegible] limestone boulders are still stinted. At the great [illegible] being worked on the Bishopthorpe Road a [illegible] *spelæus* (or *U. arctos*) was found this spring. There [illegible] be no previous record of any carnivorous remains [illegible] neighbourhood.

Glacial Sections.—The *deepest* glacial sections were [illegible] in drainage-work at the Friends' Retreat, in 1876, [illegible] feet long, cutting through the hill from north-west [illegible] south-east by east. At the highest point this was [illegible] the surface. Shafts were sunk every 30 feet. [illegible] glacial beds were met, tough boulder clays, gravels, [illegible] sand beds. The latter were variously inclined and [illegible] up, rarely continuing any great distance. Indeed [illegible] pointed to the whole mass being made up of indepen[illegible] heaped and piled against each other. The large[illegible] brought up weighed about 6,00 pounds, which is as [illegible] seen near York *in situ*, except, possibly, one still [illegible] the Mount. Some of those in the museum exceed [illegible] more. Among other stones two lumps of coal were [illegible] The most extensive series of sections are those on the [illegible] New Goods Station. For this a level was obtained [illegible] or so in extent, and 3 to 12 feet below the old [illegible] fortunately there are no records of the sections made [illegible] The stones found, though including many from the [illegible] trict, chiefly come from the Carboniferous beds [illegible] Riding. Limestones are usually scratched and often [illegible] polished. At all the places mentioned occasional [illegible] occur from Lias and Oolite beds, so that an easterly [illegible] have sometimes counteracted the prevailing set from [illegible] These glacial beds approach nearest to the purple [illegible] of Messrs. Searles V. Wood and Harmer. Plastic [illegible] ever, rather than the *moraine profonde* of an ice-[illegible] best to account for the mixture of tough boulder-clay [illegible] of boulders, gravel, and current-bedded sand. [illegible] glacial deposits are worked to depths of 30 feet and [illegible] the river-bed they may exceed 50 feet. The river [illegible] 70 feet above its pre-glacial bed, and probably 40 [illegible] the level to which it first cut down in the opening [illegible] glacial epoch.

The Devono-Silurian Formations, by Prof. E. H[illegible] F.R.S., &c.—The beds which the author proposes [illegible] under the above designation are found at various [illegible] British Isles, and to a slight extent on the Continent. [illegible] mation is, however, eminently British, and occurs [illegible] local names, of which the following are the principal:—

ENGLAND AND WALES

Devonshire.—"The Foreland Grits and Slates," [illegible] the Lower Devonian beds ("Lynton Beds").

Welsh Borders.—"The passage beds" of Murch[illegible] the Upper Ludlow Bone bed, and including the Dow[illegible] stone, and rocks of the Ridge of the Trichrug. The [illegible] the connecting link between the Estuarine Devonian [illegible] Hereford (generally, but erroneously, called the "[illegible] Sandstone") and the Upper Silurian Series.

South-East of England (Sub-Cretaceous district).—[illegible] assumed, from the borings at Ware, Turnford, and [illegible] Court Road, described by Mr. Etheridge, that the [illegible] Silurian beds lie concealed between Turnford and [illegible] Court Road on the south, and Hertford on the north.

IRELAND

South.—"The Dingle Beds," or "Glengariff Grits a[illegible] lying conformably on the Upper Silurian beds, [illegible] coast of the Dingle promontory, and overlaid unconf[illegible] either Old Red Sandstone, or Lower Carboniferous [illegible] to 12,000 feet in thickness.

North.—"The Fintona Beds," occupying large [illegible] Londonderry, Monaghan, and Tyrone, resting [illegible] on the Lower Silurian beds of Portpatrick, and overla[illegible] formably by the Old Red Sandstone, or Lower Carb[illegible] beds, 5000 to 6000 feet in thickness.

SCOTLAND

South.—Beds of the so-called "Lower Old Red Sandstone" with fish and crustaceans, included in Prof. Geikie's "Lake Orcadie, Lake Caledonia, and Lake Cheviot," underlying unconformably the Old Red Sandstone and Lower Calciferous Sandstone, and resting unconformably on Older Crystalline rocks. Thickness in Caithness about 16,200 feet. The author considered that all these beds were representative of one another in time, deposited under lacustrine or estuarine conditions, and, as their name indicated, forming a great group intermediate between the Silurian, on the one hand, and the Devonian on the other. He also submitted that their importance, as indicated by their great development in Ireland and Scotland, entitled them to a distinctive name, such as that proposed.

On the Discovery of Coal-Measures under New Red Sandstone, and on the so-called Permian Rocks of St. Helen's, Lancashire, by A. Strahan, M.A., F.G.S., Geological Survey of England and Wales.—The Trias has been penetrated, during the last few years, by three colliery shafts and three boreholes in the district bordering the St. Helen's and Wigan coal-fields on the south. It was thinner than might have been expected, while the Permian formation was altogether absent. This latter formation was believed to underlie the Trias, but to be overlapped, so as not to appear at the surface, except at St. Helen's Junction, where a marl-bed, and a soft sandstone beneath it, 30 and 90 feet thick respectively, and supposed by Messrs. Binney and Hull to be Permian marl and Lower Permian sandstone, were found in a quarry and a well. The Bold Hall Colliery shaft, at about one mile from the outcrop of supposed Permian rocks, proved the shale to maintain its thickness, but the sandstone to be 57 feet 9 inches only. The Coal-Measures were entered at 186 feet, and penetrated to a depth of 1800 feet from the surface, when the Florida Mine was met with. The red staining due to the Trias extended to a depth of 365 feet in the Coal-Measures. The Collins Green Colliery shafts, at the same distance from the boundary of the Trias, but three-quarters of a mile north-east of Bold Hall Colliery, proved the shale to be 22 feet, and the sandstone 44 feet in thickness. The latter contained spherical concretions of iron pyrites, binding the grains of sand in their original position in plains of bedding. The Coal Measures were entered at 310 feet 10 inches, and penetrated to the Florida Mine at 1667 feet 7 inches from surface. They were red for 152 feet. The dip of the so-called Permian was to the south-east at 6°, that of the Coal-Measures at 10°. The Haydock Colliery shafts (Lyme Pits), at the same distance from the boundary of the Trias, are one mile north-east of Collins Green. The shale and sandstone had diminished here to 9 feet and 7½ feet respectively. The Coal-Measures were penetrated to a depth of 97 feet 2 inches, or 413 feet 3 inches from surface. In the shafts of this and the Collins Green Colliery, the unconformity of the red sandstone and the Coal-Measures was clearly visible. The above sections show that the so-called Permian marl and sandstone thin out gradually from west to east, the lower thinning out first, and not the upper, as would have been the case if they had been unconformably overlapped by the overlying beds. They also thin out to the south, as proved by a borehole near Farnworth, three miles south of St. Helen's Junction, which, after penetrating 124 feet of yellow and white sandstone, passed through 3 feet of red and white clay, 3 feet of red sandstone, and entered purple marls with bands of limestone, belonging to the Coal-Measures. The so called Permian beds, though unconformable to the Coal-Measures, are quite conformable to the Trias, and are overlapped in consequence of an attenuation in themselves, and not through having suffered denudation before the Trias was deposited upon them. Considering also their lithological similarity to the Trias, it seems that they should be classed with this formation rather than with the Permian. The Permian rocks are probably absent west of Warrington, for two boreholes at Parkside and Winwick, commencing in the Pebble beds, entered the Coal-Measures at 291 and 341 feet respectively without encountering them. The Trias contained a bed of shale about 30 feet thick, and was based by soft sandstone with twig-shaped concretions of iron pyrites. Like the spherical nodules of Collins Green, these probably owed their origin to the action of Coal-Measure water, with sulphides in solution, acting on the colouring matter (peroxide of iron) of the Trias. The Coal-Measures consisted of purple and green marls, and at Winwick were associated with limestone. They, and the same beds found in the Farnworth boring, are precisely similar to the well-known Whiston limestone, and like it contain the *Microconchus carbonarius*. These limestones are probably the equivalents of the Ardwick limestone series in the Upper Coal-Measures of Manchester,[1] and may be found to be underlain by representatives of the coal-seams which are found in connection with it. Without doubt they must be everywhere underlain by the whole of the productive Middle Coal-Measures, but at a great and unknown depth, though there is reason to believe that the thickness of barren measures would be less in West Lancashire.

Remarks upon the Structure and Classification of the Blastoidea, by P. Herbert Carpenter, M.A.—The author and Mr. R. Etheridge, jun., who are preparing a joint memoir upon the Blastoidea, have arrived at the following conclusions respecting the group:—It is very doubtful whether the genus *Pentremites* occurs at all in Britain. Some badly-preserved fragments from the Devonian and the Scotch Carboniferous are possibly referable to it; but most of the Blastoids (besides *Codaster*) which occur in the Carboniferous Limestone belong to the genus *Granatocrinus*, Troost., which is represented by some seven or eight species. Cumberland's *Mitra elliptica* is the representative of a new genus, distinguished by the eccentric position of the spiracles. *Codaster* is a true Blastoid, and not a Cystid, as supposed by Billings. The slit-like openings of its hydrospires are nearly on the same level as the ambulacra, which do not conceal them at all. In the ordinary Blastoids, however, they are below and concealed by the ambulacra, opening externally by pores at the sides of the latter. There are various intermediate forms between these two extremes, in which the hydrospiral slits are more or less concealed by the ambulacra, but are partially visible at their sides. It is proposed to group the species thus distinguished into a genus *Pentremitidea*, which is represented in Britain by the little *Pentremites acutus*, Sowerby, in Belgium by *P. caryophyllatus*, and in Spain by *P. Pailleti*, De Verneuil, for which last the name *Pentremitidea* had been already proposed by D'Orbigny. An arrangement of this kind has been already suggested by Billings. The discoveries of Rofe, Wachsmuth, and Hambach, respecting the perforation of the lancet-piece by a longitudinal canal, are confirmed. This canal probably lodged the water-vessel, which must have been devoid of any tentacular extensions, as in some Holothurians, and in the arms of certain *Comatulæ*. Respiration was effected, however, by means of the hydrospires. The pores usually found at the sides of the ambulacra were not the sockets for the attachment of the appendages, but led downwards into the hydrospires, serving to introduce water, which made its way out through the spiracles. The genital ducts probably opened into some portion of the hydrospires, as they do into the closely similar structures of the *Ophiuroidea*, and the ova were discharged through the spiracles. Billings' statements are confirmed respecting the existence in many species of a single or possibly double row of jointed appendages along each side of the ambulacra; but these appendages are not homologous with the pinnules of the *Crinoidea*. In perfect specimens the peristome is covered in by a vault of small polygonal plates, any definite arrangement of which is rarely traceable. Extensions of this vault were continued down the sides of the ambulacral grooves, which could thus be closed in completely and converted into tunnels, as in recent Crinoids. The classification of the Blastoidea must depend entirely upon morphological principles. Mere differences in the relative sizes of the calyx plates are of very little systematic value; and differences in the numbers of side plates on given lengths of the ambulacra are absolutely worthless. On the other hand, the structure and relative positions of the hydrospires and spiracles are morphological characters of much systematic value.

On the Extension into Essex, Middlesex, and other Inland Counties, of the Mundesley and Westleton Beds, in Relation to the Age of certain Hill-gravels, and of some of the Valleys of the South of England, by J. Prestwich, M.A., F.R.S., Professor of Geology in the University of Oxford.—The author gives in this paper the result of observations commenced more than thirty years since, but delayed publication in consequence of doubts caused by the complexity of the phenomena. As mentioned in the preceding paper, a peculiar group of land, freshwater, and marine beds occupy, on the Norfolk coast, a zone between the Chillesford Clay and the Lower Boulder Clay. As we proceed southward, the land and freshwater conditions are gradually eliminated, and marine conditions then alone prevail. Poorly

[1] This identification was pointed out by Mr. De Rance in the *Trans.* Manchester Geol. Soc. for 1880. ("Further Notes of Triassic Borings near Warrington.")

Digitized by Google

marked as the marine evidence is in Suffolk, this evidence is entirely wanting further inland, and we have only levels, superposition, and structure to rely on in correlating the fragmentary outliers into which these beds finally resolve themselves. Again on the coast of the Eastern Counties, this group forms a nearly level plain but little above the sea-level, resting everywhere on an undisturbed or very slightly eroded bed of Chillesford Clay, and being succeeded, with but slight evidence of denudation, by the Lower Boulder Clay, or by the Glacial sands and gravel; whereas, as it trends inland, it attains a considerable elevation above the sea-level, passes unconformably over the older Tertiary strata, and has been subjected to a great amount of denudation. On the other hand, the old land, which seems to have extended from the eastward as far as the Norfolk coast, is now in great part below the level of the German Ocean. Further, whereas the succeeding Glacial beds all show a drift from northward to southward, this is the only case that has come under the author's notice of a marine drift from southward to the northward. The Westleton Beds, in their more typical aspect, consist of quartzose sands full of flint pebbles, almost as much worn and as numerous as in the Lower Tertiary sands of Addington. The author then proceeds to trace the beds through Essex, and gives a series of railway sections showing these beds, exhibiting usually the appearance of a white gravel, with intercalated ochreous beds, and reposing on a very eroded surface of the London Clay. In traversing the beds farther westward they undergo further modification. Certain characters remain, however, persistent, and on these we have to rely: (1) The shingle is composed essentially of chalk flint pebbles, becoming less worn as we approach the southern limits of the deposit; (2) it often becomes much mixed with flint pebbles and sub-angular fragments of compact sandstone derived from the underlying Tertiary strata; (3) the chert and ragstone fragments often so increase in numbers as to constitute a large portion of the gravel. They are worn and sub-angular, and the chert is identical with the chert of the Lower Greensand of Kent and Surrey; (4) the pebbles of white and rose-coloured quartz, of Lydian stone, and of white quartzite become rarer, and in places are wanting. The Lydian stone and some of the small quartz pebbles may be derived, with the chert, from the Lower Greensand, but this will not account for the great number of quartz pebbles found in the Eastern Counties. The quartzite pebbles are equally large, but lighter coloured and more ovoid than those of the New Red. They probably have drifted from a continental area on the east, the author having found similar beds in parts of Belgium; (5) the absence of northern drift. The author reserves for another occasion the description of the beds next in order; but he would mention here that the Boulder Clay and some Glacial gravels occupy in Herts and Berks a lower horizon than the Westleton Beds. It would therefore appear that, while the eastern area was submerged, and the strata followed in regular succession upon a surface which did not undergo denudation, the southern and western area was slowly elevated, and underwent partial denudation before the Upper Boulder Clay was deposited. Previous to the period of the Westleton and Mundesley beds, it is probable that the denudation of the Weald had hardly commenced. The area was spread over by Cretaceous strata under water at the beginning of the Crag period (the Lenham beds), and judging from the character of the beds which fringe the North Wealden area at Chelsfield, Cherry Down, &c., the author concludes that there was land south of this fringing shingle, whence the great mass of Chalk-flints and of Lower-Greensand cherts and ragstone must have been derived. This mass of *débris* serves to attest to the great extent of these strata that have been removed from the Wealden area while yet it was an elevated and not a depressed area. After the rise of the area over which the Westleton Beds extended, it underwent extensive denudation, and it was at this period that the great plain of the Thames Valley received its first outlines, although it was not until much later that the river valley received its last impress.

A Contribution to Seismology, by Prof. J. Milne and T. Gray, B.Sc.—It was pointed out that earthquake motion is generally of a very irregular character, that it usually begins gradually, reaches a maximum somewhat suddenly, and afterwards passes through several minima and maxima. The period of vibration of a great number of earthquakes observed by the authors varied between half and one-fifth of a second, while the total time of disturbance varied from one to three minutes. Reasons were given for believing that earthquakes which last for a long time are propagated further than those which last for a short time, even when the intensity of the latter is the greater. As to the determination of the origin of shock, the great value of accurate time observations was pointed out, and a sketch of different modes of making such observations was given. Explanations were entered into with regard to the rotation of bodies during earthquake shocks.

The Glacial Geology of Central Wales, by Walter Keeping, M.A.—The author adduces evidences to show that Central Wales was covered with snow and ice during the glacial period, and all the glaciers of which we have any traces were of strictly local character, each confined to its own drainage area in the present valley system. There is no evidence of any great *inlandglace*, nor of any marine submergence in recent geological time.

On the Lower Keuper Sandstone of Cheshire, by A. Strahan, M.A., F.G.S., Geological Survey of England and Wales.—The paper deals with some of the results of the re-survey of parts of Cheshire, which have been already described in detail in the Geological Survey Memoirs "On the Neighbourhood of Prestcot" (third edition), and "On the Neighbourhood of Chester." Several sections, of which the best are at Runcorn and Frodsham, show that there is a strong and constant division between the waterstones and the Keuper Basement Beds. These were formerly classed together under the name of Lower Keuper Sandstone, but, so far as the re-survey has been carried, are now distinguished on the maps. The old and new classifications may be compared as follows:—

Old Classification.	New Classification.
Keuper Marl	Keuper Marl.
Lower Keuper Sandstone ...	Waterstones.
	Lower Keuper Sandstone or Basement Beds.

SECTION D—BIOLOGY

Department of Anatomy and Physiology

On the Conario-hypophysial Tract, or the Pineal and Pituitary Glands, by Prof. Owen, C.B., F.R.S.—The author, referring to the latest contributions to the subject of his paper, remarked that they bore upon the functions of the so-termed "glands." Prof. Sapolini, in his work "L'Aire de la Selle Turcique" (8vo, 1880), concludes that "the pituitary gland secretes the fluid of the ventricles of the brain." Prof. Ed. Van Beneden, in reference to the supposed pituitary gland in Ascidians, regards it as their renal secretory organ (*Archives de Biologie*, 8vo, 1881). In pursuance of his aim, which was homological, Prof. Owen traced the modifications of the pineal and pituitary bodies and connecting parts from man down to the lowest fishes possessing a brain; and noted the progressively increased relative size and retention of tubular structure of the tract, including the so-called "pituitary gland," "infundibulum," "third ventricle," and "pineal gland," as the vertebrate series descended; also the further extension of the pineal part of the tract, beyond the brain, to its perforation of the cranium, leaving the so-called "foramen parietale" in some existing and in many extinct Reptilia. These phenomena were then traced and compared with concomitant phases in the development of the vertebrate, especially the mammalian, embryo. It was shown, as had been noted by previous embryologists, that prior to the permanent anterior outlet of the digestive sac, a protrusion from such sac extended to the large cerebral vesicle, consequently reduced to a "third ventricle"; whence the body of tract was continued onward to the epithelial covering of the head by which it was closed. The lower pharyngeal beginning of this trans-cerebral tract also became closed and modified as the "pituitary body." The upper continuation became modified and in higher vertebrates closed as the "pineal body"; but the intermediate portion of the tract retained its primitive hollow condition as the "third ventricle" and "infundibulum." The "sella turcica" in mammals, like the "foramen parietale" in cold-blooded vertebrates, were modifications in the skeleton of parts of the "conario-hypophysial tract." This tract, under all its modifications, marked vertically the division between the "cerebrum" and the "optic lobes," or divided the "fore-brain" from the "hind-brain."

The author next proceeded to point out the homologies of the parts of the neural axis in invertebrates with those of vertebrates.

The so-called "supra-œsophageal ganglion or ganglions" of the former were homologous with the "cerebrum, or cerebral hemispheres" in the latter. The so-called "sub-œsophageal masses" in invertebrates answered to the mes-and ep-encephalic

Digitized by Google

masses in vertebrates. The neural chords and ganglions continued therefrom backwards in invertebrates, answered to, or were homologous with, the myelon or spinal chord of vertebrates, in which the ganglionic structure was more or less concealed, save in some fishes, by superadded neural substances.

Now the supra-œsophageal mass, or "fore-brain," in invertebrates is divided from the subœsophageal masses, or "hind-brain," by the production of a tubular portion of the fore part of the primarily closed alimentary cavity, which, extending between those parts of the neural axis, opens upon the surface of the head so attained, and there establishes the permanent mouth; the tubular extension therefrom similarly retains its functional or œsophageal relations with the alimentary cavity. The neural chords, connecting the so-separated "fore-brain" with the "hind-brain," traversed the sides of this gullet; as the chords or "crura," proceeding to expand into the "fore-brain" of vertebrates, traverse the sides or walls of that persistent part of the conario-hypophyseal tract known in anthropotomy as the third ventricle. The large relative size of the embryonal brain-vesicle in this connection is significative of the homology of the parts extending therefrom.

Passing next to the consideration of the characters which had been held to determine the "back" and "belly" of the animal, the author cited:—"Colour," the "relative position of the body of air-breathers to the ground they stood or moved upon,"[1] and the criterion, which Cuvier adopted to determine these aspects in the notable controversy with Geoffroy St. Hilaire in 1830.[2] That criterion was the cerebrum in vertebrates, and its homologue, the super-œsophageal ganglion, in invertebrates. In an enlarged copy of the diagram by which Cuvier illustrated his position, the author pointed out the grounds on which the great French comparative anatomist exclusively applied the term brain (*cerveau*) to this part of the cerebral centres; moreover, Cuvier expressly rejects the homology of the spinal cord of vertebrates with the ganglionic chord of the body in invertebrates; and he concluded that, however his opponent might turn about his articulate or molluscous subject, the so-called brain would be on opposite sides of the alimentary canal in the two groups compared.

Now, to reconcile this difference, the author pointed out that it only needs to add to Cuvier's diagram of the brain of the mammal the conario-hypophysial tract omitted in that diagram; and, if the facts and deductions in his paper were allowed to be valid, the actual difference would lie in the atrophy of the embryonal homologue of the invertebrate gullet and mouth in vertebrates, and the establishment in them of a new entry into the alimentary cavity.

In the vertebrate embryo this anterior entry makes its first appearance as a capacious branchial or water-breathing organ, and traces of this destination are determinable in the higher vertebrates, in which the respiratory function is ultimately otherwise located and performed in relation to an aërial medium.

The entry to the alimentary cavity in Amphioxus is both a breathing and a feeding mouth: it is a vertical or longitudinal slit bounded by a pair of styles, in which is made the nearest approach to gristle of any part of the sclerous system in that primitive vertebrate. This "mouth" seems to be, or to be formed by, a confluent pair of the branchial openings, such as those which follow after it. To what pair of the costal, hæmal, or vertical side-walls or supports of the higher piscine vertebrate oral cavity, scapular, hyoid, tympano-mandibular, or palato-maxillary ribs, the parial styles of Amphioxus may be homologous, it is hard to say in the absence of skull or brain in that animal. In fishes the double function of the mouth is retained—all are "branchiostomous." In air-breathers the vertical entry becomes exclusively respiratory, and is more or less divided from the alimentary mouth beneath, and the opening or inlet to this becomes transverse by the production of the tympano-mandibular arch and its apposition to the palato-maxillary one above. In ancient forms of vertebrate air-breathers the entry to the narial passage, or respiratory mouth, as it may be termed, is by a pair of openings homologous with a piscine pair of branchial ones, but admitting air instead of water. To these "antorbital nostrils," as they are termed, in Plesio- and Ichthyosaurs, a more anterior single or confluent pair of inlets is added in Teleosaurs. In recent crocodiles the latter becomes exclusively the single, undivided, or partially divided breathing-mouth. In lizards and birds it is commonly divided, or there is a pair of "nostrils." In mammals the nostrils are commonly approximate. But the "feeding-mouth" remains below them as a distinct transverse cleft. In all these modifications the aperture, whether for breathing or feeding, or for both, is on the hæmal aspect of the brain; the vertebrates are hæmastomes; the invertebrates are neurostomes, and the chief part of their brain is "hæmad" of their mouth.

Returning to the criterion of the dorsal and ventral aspects of the animal body, the author maintained that the ganglionic body-chord in invertebrates did answer to the myelon of vertebrates; and adding this to the totality of the brain, the so-called "neural axis" was determined. So determined, he held that its position was the true criterion of the dorsal or neural aspect of the body, whether the animal moved with it next to, or farthest from, the ground, or neither the one nor the other, as in the human pedestrian.

The part or aspect of the body opposite the neural one was characterised by the location of the centre, or chief centres, of the vascular system, and this had led Prof. Owen, at the commencement of his anatomical teaching, to term it the "hæmal aspect."

Referring, finally, to the diagram of the invertebrate and vertebrate animals in corresponding positions, agreeably with the above criterion, the author showed that the so-called "brain" (Cuvier), or the supra-œsophageal brain-mass of comparative anatomy, was not above, but below, the mouth or gullet in invertebrates, and that the sub-œsophageal mass was above the mouth or gullet; also that the reverse relative positions were due to the atrophy of the primitive homologues of such entry in vertebrates, and the substitution of another opening or conduit to the stomach, whereby these anterior openings and conduits are on the lower or hæmal side of the cerebrum in vertebrates, on the upper or neural side of the cerebrum or fore-brain in invertebrates. In briefer terms, the one division was "hæmastomous"; the other division was "neurostomous." The paper was illustrated by drawings, of which enlarged diagrams were exhibited to the Section.

Dr. Montagu Lubbock's paper *On the Development of the Colour Sense* discussed the question of the evidence as to the acquirement of the power of perceiving colour by man within historical times, and also the question whether this perception had been gradually acquired by man or any animal at any time. He concluded that there were good grounds against believing that any such gradual development in the case of man could be proved; and while it was probable that in those animals which lived upon coloured food the power of appreciating colour would gradually arise, yet there was no proof of this yet available, and no idea could be given of the stages by which this had been brought about.

Prof. S. P. Thompson read a paper upon the *Function of the two Ears in the Perception of Space*, in which he stated his view as follows:—Judgments as to the direction of sounds are based in general upon the sensations of different intensity in the two ears; but the perceived difference of intensity upon which a judgment is based is not usually the difference in intensity of the lowest or fundamental tone of the compound sound, or "clang," but the difference in intensity of the individual tone or tones of the clang for which the intensity-difference has the greatest effective result on the quality of the sound. Prof. Thompson further remarked that now that the physical bases of the problem were laid down, the acoustic perception of space might be greatly elucidated by experiments upon persons possessed of abnormal hearing, and upon the blind, in whom this perception is abnormally developed.

Prof. J. C. Ewart of Aberdeen gave an account of the researches *On the Influence of Bacilli on the Production of Disease*, which he has communicated to the Royal Society.

Mr. W. A. Forbes read a paper *On the Incubation of the Indian Python* (*Python molurus*), *with special regard to the alleged Increase of Temperature during that Period*. This paper gave an account of a large series of observations made during the last season in the gardens of the Zoological Society. The python laid about twenty eggs, and incubated for about six weeks. Observations were made upon both male and female, kept in adjoining cages under conditions approximately identical, and it was found that there is an increase of temperature in the incubating female analogous to that which occurs in birds; the amount of increase observed was not so great as others had

[1] The anatomists who adopt this criterion call the hæmal aspect of the lobster its "back," the neural one its "belly"; the right side of the animal is its left side, and *vice versâ*.

[2] Reference was here made to the nineteenth vol. of the *Annales des Sciences Naturelles* for 1830 (March), p. 241, Pl. XII.

Digitized by Google

tated, being about 1°9' and 3° Fahrenheit, according as the temperature was taken on the surface of the body or between its folds.

Dr. D. J. Cunningham's paper *On the Structure and Homologies of the Suspensory Ligament of the Pelvis in the Horse, Ass, Ox, Sheep, and Camel*, described the particular members of the intrinsic group of muscles which enter into the formation of this ligament. He showed further that the process of transformation of muscle to ligament seemed to be effected by a fatty degeneration of the muscle-fibres with a coincident multiplication of the connective-tissue elements of the muscle; that muscular tissue may exist in the body and have no apparent function, unless it were a purposeless contraction, stimulated by the nerve-supply it received from nerves contained within the ligament. In the transformation the nerves remained unchanged; in the sheep, in which there is not a trace of muscular tissue left, the nerves were relatively as large as in the ox or horse.

Other papers were read, by Prof. Struthers, *On the Acetabulum of Animals in which the Ligamentum teres is described as existing*, and *On the Correspondence between the Articulations of the Metacarpal and Metatarsal Bones in Man*; by Mr. F. M. Balfour, *On the Nature of the Pronephros, or so-called Head-Kidney of Adult Teleosteans and Ganoids*; by Mr. G. E. Dobson, *On the Digastric Muscle, its Modifications and Function*; and Dr. W. H. Stone, *On the Effect of the Voltaic Current on the Elimination of Sugar*. Altogether fourteen papers were read before this department, which only sat on two days. Half the papers were anatomical, and half physiological. It is to be assumed that the energies of anatomists and physiologists had been so largely occupied with the International Medical Congress that no novelties could be produced on this occasion.

Department of Anthropology

Miss A. W. Buckland, in a paper *On the Geographical Distribution of Mankind*, discussed the problems awaiting solution in anthropology, especially the relations of brachycephalic and dolichocephalic peoples, and the questions of the unity of the race, and of the peopling of oceanic islands and of Australia. She considered that nothing definite could as yet be determined regarding any of these matters.

Mr. Staniland Wake read a paper *On the Papuans and the Polynesians*, in which he came to the conclusion that the primitive stock from which both had sprung was now represented by the Australian race, which had formerly a much wider extension than at present. The existence of two types among the Australians showed they were not a pure race, being probably intermixed with the Negrito. The Polynesians showed considerable traces of this intermixture, while the Papuans had been largely affected by contact with a more modern Asiatic people now represented by the Malays, having been further specially influenced by the intermixture of Arab and Indian blood.

General Pitt-Rivers gave an account of *Excavations in the Earthwork called Ambresbury Bank in Epping Forest*, which showed that it was a camp of British erection, but it was not possible from the excavations made to determine whether it was made before or after the Roman conquest. General Pitt-Rivers read another paper *On the Entrenchments of the Yorkshire Wolds and the Excavations in the Earthwork called Danes' Dyke at Flamborough*, in which he showed that the term Danes' Dyke was undoubtedly a misnomer, for the whole district was the scene of the operations of a much earlier people, who were formidable in their means of offence and defence, and in the discipline necessary to construct the entrenchments, which extended for great distances. At Danes' Dyke he found both flints and flint flakes, showing that the defenders of the earthwork used flint, and lived not later than the bronze period, at the period of the tumuli of the Yorkshire wolds. In a further communication General Pitt-Rivers described his discovery of flint implements in stratified gravel in the Nile Valley, near Thebes.

Dr. Beddoe gave an interesting abstract of results *On the Stature of the Inhabitants of Hungary*, based on recruiting statistics. The average Hungarian soldier was about 5 feet 5¾ inches high. The Germans and Croats gave taller men than the Magyars. The citizens of Budapesth were taller than countrymen at the age of twenty. In five western counties (including Pesth), where the population was mainly Magyar, the mean stature at twenty-five years might be taken as 5 feet 5·2 inches.

A paper *On the Physical Characters and Proportions of the Zulus*, read by Mr. Bloxam, gave the details of an examination of sixteen male and three female Zulus brought to this country and measured in the presence of Prof. Flower, Gen. Pitt-Rivers, Mr. Roberts, and Mr. F. Galton. It appeared that the average stature of the males was 67·3 inches, nearly half an inch less than the average Englishman of the same age; the average chest girth was 36·5 inches; Englishmen 38·5; the average weight: Zulus, 131 lbs.; Englishmen 142 lbs. Of course the Zulus, being exhibitors for their district in throwing accomplishments, were in high training, and were developed in muscle.

Mr. E. F. im Thurn, in a paper *On the Aborigines of Indians of British Guiana*, dwelt at some length on the confusion introduced by the application to animism of the terminology and conceptions of higher religious systems. The Indians of Guiana had an animism of a very pure type, possessing very little affected by the modifications which always arise into higher religion. They had no belief in the existence of the spirit, no ideas corresponding to heaven and retribution, no knowledge of purely spiritual beings, gods, and no worship, though certain acts were practised to avoid attracting the attention of malignant beings.

Mr. Park Harrison, in exhibiting a collection of photographs of types of different races in the British Islands and elsewhere, urged the necessity, for the purposes of scientific comparison, of having photographs taken of uniform size, both in front and sufficiently in profile to show the brow, the prominence of the nasal bone, and also the form of the ear, which appeared to be a racial characteristic, though much disguised by modern dress. This, however, would be attended with expense which the Anthropometric Committee could afford. Prof. Flower, commenting on this communication, said the subject had not yet been fairly attacked in this country; it was only by photographing of numbers in each part of England that we could ultimately have a chance of arriving at the types of the various races that had contributed to the mixtures now prevailing. There was great difficulty in forming an opinion as to what types were really represented; no doubt the comparison of photographs, done on a certain scale, would be of much value in this matter.

The Anthropological Department sat on five days, and the seven papers or reports were presented to it. Among those that we may particularise as of interest were those by Mr. C. Mortimer, *On Six Ancient Dwellings found near the Barrows on the Yorkshire Wolds*; Mr. Francis Galton, *On the Application of Composite Portraiture to Anthropological Inquiry*; Mr. J. Harris Stone, *On the Viking Ships discovered at Gokstad, Norway, in 1880*; Mr. Hyde Clarke, *On the Early Civilisation of Cyprus and Attica, and its Relation to Babylonia*; Mr. Stokes, *On Traces of Man in the Crag*; Prof. T. McK. Hughes and Mr. A. W. Wynn, *On the Age of the Deposits in the Cave of Cefn, near St. Asaph, with special reference to the Date of the first Appearance in them*.

Department of Zoology and Botany

Sir John Lubbock's paper *On the Sense of Colour* in bees first dealt with Bonnier's experiments on bees, and showed the fallacies in them, which were avoided in a series of his own observations recently made. He took slips of glass 3 inches generally used for microscopic work, and pasted on them paper coloured blue, green, orange, red, white and yellow. He induced a bee to visit all in succession when covered by the slip on which was a drop of honey. Then the honey and bee were removed, and the situation of the coloured glasses changed; when the bee returned from the hive the number of visits to particular colours was noted, and the result of different experiments was that blue was the bee's favourite colour, then white, yellow, and green. The observations were repeated in several different ways, with the same results. The question naturally arose, How then are there so few blue flowers? Sir John believed that all flowers were originally green, and that they have passed through stages in which they were white or yellow, while many have become red, and finally blue. This was supported by facts such as the following:—In Norway many simple open flowers, as buttercups, were yellow or white, while the blue delphiniums and aconites were of highly specialised form, and therefore probably of more recent origin. Among the Caryophyllaceæ the red and purplish colours were among those with highly specialised flowers, while the simple flowers, as stellaria and cerastium, were mostly white. In violets many of the most highly specialised forms were blue, the simpler ones yellow. In gentians, heath, the

Digitized by Google

species have long tubular flowers specially adapted to bees and butterflies, while the yellow gentian has a simple open flower with exposed honey. Sir John also described his experiments made on daphnias by illuminating a trough with an extended solar spectrum in such a way that after a given lapse of time he could isolate the portion of the trough illuminated by each principal colour, and count the number of daphnias in it. They appeared to have a very predominant preference for the red and yellow and greenish yellow and green. He also found, contrary to the conclusion of M. Paul Bert, that they clearly perceive the ultra violet rays.

Sir John Lubbock read a paper *On the Mode in which the Seed of Stipa buries itself in the Ground.*—One of the most interesting parts in botany, he said, was the consideration of the reasons which led to the different forms, colours, and structures of seeds; and it was, he thought, pretty well made out that a large proportion of those might be accounted for either as serving to protect the seed or to assist in its conveyance to a place suitable for its growth. If the seeds of trees fell directly to the ground it was obvious that very few of them would have a chance of growing. It was an advantage to them, therefore, of which many availed themselves, to throw out wings, in consequence of which the wind wafted them to a greater or less distance. Others, such as the whole tribe of nuts, being edible, were carried about by beasts and birds, and though some were sacrificed, others survived. Fruits, again, in consequence of their sweetness, were carried about by animals, which, after partaking of the fleshy portion, dropped the seeds themselves. Many seeds were covered with hooks, and thus, adhering to the wool of sheep and other animals, were carried to greater or less distances. Others, like those of our common dandelion, were provided with fairy parachutes, and were thus borne away by the wind. Others again, like some of the violets, geraniums, vetches, brooms, cucumbers, cardamine, oxalis, and others, had beautiful and varied contrivances, by which they actually threw the seeds to a distance, in some cases of more than 20 feet. Others, again, were enabled to penetrate the earth, and thus sow themselves in the ground. In one of our English clovers, *Trifolium subterraneum*, after the flower had faded, it turned downwards, and buried itself in the ground. The ground nut of the West Indies, and more than one species of vetch, had a similar habit. In the *Erodiums* or Crane-bills, the fruit is a capsule, which opens elastically, and as in the case of the allied geraniums, sometimes threw seeds to some little distance. The seeds themselves were spindle-shaped, hairy, and produced into a twisted awn. The number of turns on the awn depended upon the amount of moisture. Mr. Rowe, to whom they were indebted for an account of their mechanism and mode of action, said if a seed be laid upon the ground, it remained quiet as long as it was dry, but so soon as it was moistened the outer side of the awn contracted, and the hairs surrounding the seed moved outwards, the result of which was to raise the seed into an upright position. The awn then gradually unrolled, consequently elongating itself upwards, with the result that if it was entangled amongst any of the surrounding herbage, the seed was forced into the ground. A still more remarkable case was that of the *Stipa pennata*. The actual seed was small, with a sharp point, and with stiff short hairs pointing backwards. The upper end of the seed was continued into a fine twisted rod; then came a plain cylindrical portion attached at an angle to the corkscrew, and ending in a long and beautiful feather—the whole being about a foot in length. That end was supposed by Mr. Francis Darwin, to whom they were indebted for a very interesting memoir on the subject, to act very much in the same manner as that of *Erodium*, already mentioned. He did not doubt that the end would bury itself in the manner described by Mr. Darwin, but he doubted whether it always did so. One fine day, not long ago, he chanced to be looking at a plant of that species, and around it were several seeds more or less firmly buried in the ground. There was a little wind blowing at the time, and it struck him that the long feather awn was admirably adapted to catch the wind, while on the other hand it seemed almost too delicate to drive the seed into the ground in the manner described by Darwin. He therefore took a seed and placed it upright on the turf. The day was perfectly fine, and there could therefore be no question of hydroscopic action. Nevertheless, when he returned after a few hours, he found that the seed had buried itself some little distance in the ground. He repeated the observation several times, always with the same result; thus convincing himself that one method, at any rate, by which seeds bury themselves is by taking advantage of the action of the wind, and that the twisted position of the awn, by its corkscrew-like movement, facilitates the entry of the seed into the ground.

Mr. A. W. Bennett read a paper *On the Constancy of Insects in Visiting Flowers*. He said he was not aware that attempts had yet been made to determine the question whether insects were altogether discriminating in their visits to flowers, or whether on the same journey they confined themselves exclusively or chiefly to one species. That paper, which was the result of observations during the fine weather of the last two years, was intended as a contribution towards the settlement of that question, obviously one of some importance in relation to the cross fertilisation of flowers by insects. Those who had not made the experiment would hardly appreciate how difficult it was to watch continuously for any considerable period the flight of any insect. He had chosen in all cases as points of observation spots where a considerable number of different flowers grew in profusion, and were intermixed, so that the insect would have abundant opportunity of changing its diet if so disposed. In recording the number of flowers of the same kind visited by an insect in the same flight, he always meant flowers at such a distance from one another that the insect had to use its wings in getting from one to another. In August of last year he observed three different flights of the "painted lady" butterfly, and it settled six, three, and ten times respectively, always confining itself to the same species of flower. On the same plot a hive-bee paid nine successive visits to the same species of flower. On another plot a bumble-bee visited the same species of flower fifteen times, and another of the same species eleven times in succession, not touching any other flower, but passing over many. Mr. Bennett gave further results of his observations on different occasions and in different parts of the country. In order to test whether insects were guided by colour only when visiting flowers, he watched one spot where there were white and purple foxgloves, but a large bumble-bee was seen to enter sixteen of the flowers regardless of colour, although to find the succession of foxgloves it had to fly considerable distances over other flowers. No general statement could be made as to the consistency of insects in visiting the same species of flower during the same flight. A decided preference for successive visits to the same flower was unquestionably shown in many instances, but those visits did not depend on the colour of the flower only. The hive-bee appeared to be by far the most constant in that respect, often absolutely so. From their strong and rapid flight and extremely hairy covering of their abdomen, that class of insects was probably the most efficient agent in the dissemination of pollen. So far as could be gathered from observation, the "painted lady" and the small tortoise-shell butterflies were very consistent, while the whites, the blues, and the browns were far from catholic, or less discriminative in their tastes. It was open to question, however, whether more than a very few flowers were dependent upon butterflies for their fertilisation. At all events their visits to flowers were often only interludes in their settlements on grass, leaves, the stems of trees, or the bare ground.

Prof. O. C. Marsh of Harvard, U.S., contributed one of the most attractive papers to this department, *On Jurassic Birds and their Allies*. He detailed the results of his examination of the Archæopteryx in the British Museum, the more recently discovered specimen at Berlin, and of Compsognathus in the Munich Museum, as compared with the forms previously made known by himself in America. His impression was that the two specimens of Archæopteryx were specifically identical, although fuller evidence might prove them to be distinct. He still considered that we knew little that could determine how or at what period birds originated. At present the four oldest known birds were as distinct from one another as any birds of the present day. Yet if he were asked to distinguish between the bones of a reptile such as Compsognathus and a bird such as Archæopteryx, if broken up and mixed together, he should be puzzled to do it. Prof. H. G. Seeley, in the subsequent discussion, stated his belief that the British Museum Archæopteryx was not merely specifically, but generically distinct from that at Berlin.

Dr. A. A. W. Hubrecht of Leyden gave an interesting exposition of *The Structure and Affinities of Proneomenia*, one of the valuable finds of the *Challenger* Expedition. Dr. Hubrecht spoke in excellent English, and was listened to with much appreciation.

Mr. Forbes gave an account of his work *On the Anatomy ana*

Digitized by Google

Classification of the Petrels, based upon those collected by the *Challenger* Expedition. He divided them into two main families —the Oceanitidæ or Oceanic Petrels, with four genera and seven species, and the Procellariidæ, divisible into three sub-families of albatrosses, diving petrels, and true petrels. As to descent, he considered the petrels were probably much modified descendants of some ancient form related to the ciconiform birds of Garrod, *i.e.*, the storks, American vultures, and their allies. Mr. P. H. Carpenter, M.A., read papers *On the various Larval Forms of Comatula*, and also *On the Species of British Comatula*. Other zoological papers of interest were by Prof. Busk *On the Use of the Chitinous Appendages of the Skeleton in the Cheilostomatous Polyzoa in the Diagnosis of Species*; Mr. W. T. Blanford, F.R.S., *On our Present Knowledge of the Fauna Inhabiting British India and its Dependencies*; Mr. P. A. Geddes, *Notes on Chlamydomyxa*, and *On a New Sub-Class of Infusorians*; Gen. Sir J. E. Alexander, *On the Improvement of Freshwater Fisheries*, and a further report was made *On the Marine Zoology of South Devon*.

Among other botanical communications we may note those of Mr. J. G. Baker, F.R.S., *On the Botany of Madagascar*; of Mr. A. W. Bennett *On the Colours of Spring Flowers*; of Mr. Joseph Lucas *On some Vestiges of the Ancient Forest of Part of the Penine Chain*. The department sat during five days, and twenty-eight communications were disposed of, including twenty zoological and eight botanical; the latter, however, fully divided the interest with the former, owing mainly to the papers of Sir John Lubbock and Mr. Bennett.

NOTES

Dr. Rudolph König of Paris, whose acoustical fame is world-wide, is about to publish in one volume, in the French language, his remarkable researches in acoustics, which have appeared at intervals in the *Annalen der Physik* and elsewhere, during the past fifteen years. The work will, we understand, be liberally illustrated with drawings of the newer and more important pieces of apparatus which Dr. König has invented.

M. Pasteur, it is stated, has resolved to visit the Bordeaux lazaretto to study yellow fever, and ascertain whether it is due to a parasite, and can be guarded against by inoculation.

The building of the Observatory of the Pic du Midi has been completed on the very top of the mountain, at an altitude of 2600 metres. The old building, which was placed in a valley at a less elevated situation, will be used merely as a station for travellers. General Nansouty is now busy fitting the establishment with apparatus and victuals for next winter, as, according to every probability, it will be blocked by snow during more than six months. The storms are so heavy that not less than six electric light conductors have been established for protection.

The autumn meeting of the Iron and Steel Institute will be held in London this year, on October 11–14, at the Institute of Civil Engineers, under the presidency of Sir Henry Bessemer, F.R.S. Numerous excursions have been arranged for, and the following papers are announced to be read:—On the manufacture of steel and steel rails in the United States (supplementary paper), by Capt. W. R. Jones, Pittsburg, Pa.; on a method of securing homogeneity in the Bessemer process, by Mr. W. D. Allen; on the manufacture of ordnance at Woolwich, by Col. Maitland; on the application of wrought iron and steel to the manufacture of gun carriages, by Mr. H. Butter; on the manufacture of projectiles, by Mr. J. Davidson; on the distribution of elements in steel ingots, by Mr. G. J. Snelus; on the use of brown coal in the blast furnace, by Prof. P. Ritter von Tünner, Leoben, Austria; on certain physical tests and properties of steel, by Mr. Edward Richards; on the tin-plate manufacture, by Mr. Trubshaw; on the use of American anthracite in the blast furnace, by Mr. J. Hartman, Philadelphia; on variation of elements in cast-steel ingots, by Mr. F. Stubbs; and on the recent progress of the basic Bessemer process, by Herr Paul Kupelweiser, director of the Witkowitz Works, Austria.

Great preparations are being made in Dublin for the forthcoming meeting of the Social Science Congress, which begins its sittings there on the evening of Monday, October 3, when Lord O'Hagan, as president, will deliver the inaugural address in the Exhibition Palace. Among the other addresses to be given are the following:—"On Education," by Sir Patrick J. Keenan, K.C.M.G., C.B.; "On Health," by Dr. Cameron, M.P.; "On Economy and Trade," by Mr. Goldwin Smith; and "On Art," by Lord Powerscourt. During the week garden parties and *conversazioni* will be given by some of the leading citizens and learned societies.

Baron Mikluho Maclay, before leaving Sydney, gave the Linnean Society of New South Wales on July 25 a short account of the progress of the Sydney Biological Station at Watson's Bay, which has been opened through his energies, an account of which we recently gave some account. The building was to be ready in a week's time, Dr. Maclay stated. The Royal Society of Victoria have agreed to assist the establishment of the station, not only by personal subscription, but also by an annual grant from the funds of the Society. This last decision is most important, opening the prospect of a permanent, moderate, subsidy for the support of the institution. The Royal Society of New South Wales will also probably, on the representation of the President at the last annual meeting, follow a similar course. "I entertain the hope," Dr. Maclay said, "that the establishment of the Biological Station of Sydney will very probably induce the other colonies to follow this good example and will be the means of uniting the scientific societies of different colonies. That the Biological Station of Sydney will not remain long isolated in this part of the world is a fact, as Dr Hector told me that he intended to establish one in New Zealand. The establishment of an Intercolonial Biological Association, which should have for its object to assist in the formation, maintenance, and regulation of biological stations in Australia, was a plan which, in my opinion, ought not to remain long a *pium desiderium* only. Therefore I called a public meeting, June 15, with the object—1. To obtain a number of yearly contributors, as the subsidy from the Government is in proportion to the public subscription, and the yearly subsidies from the Royal Society of New South Wales and Victoria are very moderate. 2. To frame rules for the station. From the gentlemen present at the meeting a committee was chosen for the discussion of the proposed rules, this committee consisting of six members, of which four are at the same time trustees of the Biological Station; after four meetings, agreed to a code of rules, which will be submitted to the trustees of the Biological Station." Certainly science in Australia is greatly indebted to the intelligent energy of the Russian naturalist, and we trust the work so well begun will be continued without abatement.

The Epping Forest and County of Essex Naturalists' Field Club's annual Cryptogamic meeting is advertised for Saturday, October 1. The Club is to be congratulated for the list of well-known botanists who appear as referees and conductors. Thus for Fungi we see the names of Dr. M. C. Cooke, M.A., F.L.S., Mr. Worthington Smith, F.L.S., Dr. H. T. Wharton, M.A., F.L.S., and Mr. James English; whilst for Mosses and Lichens the names of Dr. Braithwaite, F.L.S., and Mr. E. M. Holmes, F.L.S., are announced.

The Yorkshire Naturalists' Union will have a Fungus Foray on Friday and Saturday, September 30 and October 1, at which they will gladly welcome any mycologists who may be disposed to assist them. The Friday's programme is to consist of an excursion in the neighbourhood of Harrogate. On the Saturday is to be a "show," at which will be exhibited fungi, and any objects illustrative of the subject which may be sent. The [illegible] the evening of Saturday. Arrangements are [illegible] ch localities in all parts of Yorkshire f[illegible]; and at the meetings the Union will [illegible]

Digitized by Google

honoured by the presence of Messrs. W. Phillips, C. B. Plowright, G. Massee, and Rev. J. E. Vize.

No less than ten observers are now engaged at the Observatory of Paris in the completion of the catalogue of stars which was begun by Leverrier. The work is progressing at an unprecedented rate, not less than 70,000 observations having been tabulated, after having been duly reduced in a single year. Admiral Mouchez has taken possession of the new Observatory grounds, and the earthworks for the foundation of the great refractor building, and the construction of the underground chambers in which the magnetic observations are to be conducted, is being continued.

DURING the York session of the British Association a most successful half-yearly meeting of the members of the Natural History Society of the Friends' School in Bootham was held in the lecture-room of that establishment. Among those present were Prof. S. P. Thompson, F.R.A.S., J. G. Baker, F.R.S., A. W. Bennett, F.L.S., J. Edmund Clark, F.G.S., Thomas Gough, M.A. (of Elmfield College), Rev. T. A. Preston, M.A. (Science Master of Marlborough College), Dr. W. W. Newbould, Langley Kitching, Ed. Grubb, M.A., Hugh Richardson, R. M. Christy, A. J. Wigham, with J. F. Fryer, B.A. (the present head master), Fielden Thorp, B.A. (the former superintendent), who presided, and many others. Dr. D. Hack Tuke delivered an interesting address strongly advocating the study of science. Mr. Baker of Kew said that a large measure of his success in life was due to the early scientific training he had received when a member of this society. Many other interesting addresses were given by those present. The Society is only three years younger than the British Association itself, having been formed on August 14, 1834. Since that time many ardent naturalists, now well known to science, had passed through its ranks.

A CORRESPONDENT from Kingussie, in Inverness-shire, writes: "We had just (Sunday, 18th) been reading somewhat sceptically the paragraph about the pink rainbow, when behold, to our astonishment, there appeared just over Glen Feshy the most lovely pink rainbow you can imagine, shaded from crimson to pale pink, but no other colour. It was strange and beautiful, and none of us had ever seen anything like it before."

THE just-issued volume of the *Proceedings* of the Natural History Society at Berne (Nos. 979-1003) contains, besides minutes of proceedings and small notes, several valuable papers: by Prof. Studer, on the segmentation of Madreporaceæ, on the corals of Singapore, and on the statistical researches as to the colour of eyes and hair of children in the canton of Berne; by Dr. Graf, on the specific heat of gases at constant volume; on glacial deposits at Berne, by M. Bachmann; on the intrusion of limestones into the crystalline rocks of the Finsteraarhorn, on the dependence of organisms upon oxygen, and on the influence of poisons on invertebrata, by Dr. Arnold; and several anatomical notes by Prof. Luchsinger.

WE have received the *Proceedings* of the sixty-third annual meeting of the Swiss Society of Naturalists, which was held in September last year at Brieg. They contain the address of the president, M. Wolf, and minutes of proceedings of the sections, among which we notice communications:—by Prof. Rütimeyer, on the metamorphoses of skulls; by Prof. Yung, on his physiological researches on cephalopods at the Naples Zoological Station; by M. Lory, on geological researches on the Finsteraarhorn; and by M. de la Harpe, on the nummulitic formation in Switzerland. In the Reports of Commissions we notice the report, by Prof. Rütimeyer, on the important work, by M. Ph. Gosset, on the glacier of the Rhone, to which the Schläfli Foundation was awarded. This immense work, which is the result of six years' consecutive measurements of the positions of no less than 156 numbered and painted blocks, carefully chosen on the surface of the glacier, as well as of surveys on the scale of 1 : 5000, contains a thorough description of the glacier of the Rhone, and is accompanied by a most elaborate map of the glacier, numerous transverse and longitudinal sections, and several sheets of drawings, which show the results of the the measurements as to the motion of the glacier.

STATISTICAL researches as to the colour of the hair and eyes of children had been made in all the cantons of Switzerland, with the exception of Berne, Geneva, and Tessino. The investigation as to the first of these cantons is now terminated, and the results of the examination of 94,221 children are published by Prof. Studer in the *Proceedings* of the Berne Society of Natural History (No. 986), and are accompanied by four coloured maps, which show graphically the results. It is seen from these researches that in the canton of Berne the dark type prevails over the fair, but that the pure types are not so numerous, especially in the central parts, as the mixed ones. The pure fair type, which makes 9 to 11 per cent. in the north-eastern parts of the canton, increases to the south (11 to 14 per cent. in the middle parts, and 15 to 20 per cent. in the Alps), and reaches its highest percentage in the secluded valley of the Saanen (28 per cent.). The dark type is most numerous in two regions—that of the western lakes and Old Rhætia (21 to 29 per cent.), whilst in the middle parts it reaches only 21 to 25 per cent., and only 16 to 20 per cent. in some secluded valleys. After having shown the distribution of mixed types, Prof. Studer considers these data in connection with history, and comes to several interesting conclusions.

MESSRS. SONNENSCHEIN AND ALLEN have issued a second edition of Prantl's "Elementary Text-book of Botany," revised by Dr. S. H. Vines, who has made considerable alterations in the book, with the view of increasing its usefulness. The most important alteration, it is stated, is the adoption of a Classification of Flowering Plants which will be more familiar to English students than that which was followed in the first edition.

A RECENT speech of the Governor of Hong-kong, Sir John Pope Hennessy, contains an interesting account of the spread of vaccination amongst the Chinese in the Colony and on the neighbouring mainland. No port in the world is more liable to a visitation of small-pox, yet it never spreads there. The health-officer of the Colony also was astonished to find that nearly all the young Chinese emigrants had vaccination or inoculation marks upon their arms. He says he was often puzzled to know how this vaccination came to be apparently so perfect among the Chinese. On inquiry it turned out that the native doctors of the Tung-wa Hospital—a charitable institution supported by the voluntary contributions of Chinese—not only vaccinated their countrymen in the Colony itself, but actually sent travelling vaccinators over the adjoining provinces of China. In this way thousands of people have been vaccinated during the last four years. The lymph is supplied them by the Governor, who gets it every mail in his despatch-bag from Downing-street. Three dentists also appear in the census of the professions of the Colony. "About eighteen months ago," adds his Excellency, "I visited one, not professionally, but for the purpose of seeing the instruments he used, and I then found he had the same apparatus we find in all dentists' establishments. In fact he did work for the first-rate American dentists we have here, being fully capable of making or repairing sets of teeth. He was a gentleman of intelligence, and impressed me, I must say, as favourably as a dentist could."

THE Congress of Orientalists has had a very successful meeting at Berlin. Of the International Geographical Congress and

Digitized by Google

Exhibition at Venice, we hope to give a detailed report next week. An Archæological Congress was opened at Tiflis on Tuesday; among the delegates is Prof. Virchow. The Caucasus Museum was also opened; the collections were very numerous and varied.

THE ensuing session of the Aristotelian Society for the Systematic Study of Philosophy will open on October 10, at 20, John Street, Adelphi, W.C., with an address by the president, Shadworth H. Hodgson, LL.D., and the Society will thereafter continue its historical studies, alternated with discussions of philosophical questions.

WE gladly welcome the appearance of the "Phænogamous and Vascular Cryptogamous Plants of Michigan," by Charles F. Wheeler and Erwin F. Smith (Lansing, 1881). 1559 species of flowering plants are enumerated, and 75 of horsetails, ferns, and lycopods. The arrangement followed is that of the fifth edition of Gray's Manual, and the authors promise to publish addenda from time to time.

WE have received the first part of Fr. Westhoff's "Käfer Westfalens," forming a supplement to the "Verhandlungen des naturhistorischen Vereins der preussischen Rheinlande und Westfalens," Jahrgang 38 (1881). It is only a List, prefaced by remarks on the district, and with list of authors, &c., but it promises to be of value on account of the thorough manner in which it appears to be worked out, and the beetle-fauna appears to be rich. Adopting the latest European Catalogue as a basis, this first part extends to the *Heteromerida*. No new species are described, but several apparently new varieties in the *Carabida* and water-beetles receive names.

UNDER the direction of the Council of the Meteorological Society, Mr. W. Marriott has issued "Hints to Meteorological Observers, with Instructions for taking Observations, and Tables for their Reduction" (Stanford). Many of our readers might be able to turn these Hints to good practical account. We have also received the first number of the *Meteorological Record*, containing the monthly results of observations made at the stations of the Meteorological Society, with remarks on the weather for the quarter ending March 31.

THE Report of the Committee of the Queenwood College Mutual Improvement Society for the end of the summer term 1881 is interesting, showing that much useful and varied work is being done by the Society.

THE additions to the Zoological Society's Gardens during the past week include a Malbrouck Monkey (*Cercopithecus cynosurus*) from West Africa, presented by Mrs. Paterson; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. Harding Cox; a Rutiginous Cat (*Felis rubiginosa*) from Ceylon, presented by Mr. Charles E. Pole Carew; a Brown Bear (*Ursus arctos*) from Russia, presented by Messrs. Morgan, Gellibrand, and Co.; two Chukar Partridges (*Caccabis chukar*) from India, presented by Col. Thos. Pierce, 16th Regt. Bombay N.I.; two Dwarf Chameleons (*Chamæleo pumilus*) from South Africa, presented by Mr. Duncan W. B. Swaine; two Spanish Terrapins (*Clemmys leprosa*) from Spain, presented by Major Rooke; a Illumined Snake (*Morelia spilotes*) from Australia, presented by Mr. C. C. Sharratt; two Cape Cranes and Cranes (*Balearica chrysopelargus*), two Wattled Cranes (*Grus carunculata*) from South Africa, deposited; a Black-faced Spider Monkey (*Ateles ater*) from South America, on approval.

PHYSICAL NOTES

DR. R. KÖNIG has just completed a new instrument—a variety of the wave-siren which we recently described—with which he proves an extremely important fact, which probably is new to all acousticians, namely, that the quality of a compound tone is very distinctly affected by differences of phase [illegible] An account of these last researches will be found in [illegible] coming number of *Wiedemann's Annalen*.

DR. KÖNIG describes (*Wied. Ann.*, No. 8) a way of [illegible] the interior of organ-pipes (especially stopped ones) [illegible] action, without disturbing the vibrations. The [illegible] central longitudinal slit made in the back, and [illegible] front, with scale, is supported horizontally in a [illegible] the slit and half the back of the pipe dips in [illegible] brass tube, bent twice at a right angle, is supported [illegible] so that one end enters the slit to about the middle [illegible] This tube can be slid along the pipe, and is connected [illegible] caoutchouc tube to the ear, a metronomic [illegible] Passing through a ventral segment, one notices a [illegible] weakening of the sound, then a sudden strengthening [illegible] stroke of a bell). By noting such points the position [illegible] segment can be exactly determined. Dr. König [illegible] results which apparently fail to accord with theory. He [illegible] describes a drum-like arrangement for exploring [illegible]

AN extremely ingenious piece of electric [illegible] being shown in the Electrical Exhibition at Paris. [illegible] apparatus by which any number from 1 to 999 [illegible] signalled on one wire by a single movement of the [illegible] figures appearing at the distant end at an opening [illegible] describe the details of this apparatus would take too long. It is the invention of Mr. J. Mackenzie.

M. COREU has constructed a polarising prism [illegible] film of Iceland-spar fixed with Canada balsam between [illegible] flint-glass prisms. The polarisation is far from perfect, [illegible] and the field is very narrow, so that the instrument, [illegible] interest from a theoretical point of view, is of little practical value.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—An examination will be held at Exeter [illegible] Thursday, October 13, for the purpose of filling up a [illegible] Science Scholarship, tenable for four years during [illegible] The examination will be in biology, chemistry, and [illegible] Candidates will be expected to show proficiency in at least [illegible] of these subjects, and the scholar will be required to [illegible] honours in biology in the Natural Science School. The [illegible] papers will be set in chemistry and physics as to the [illegible] for the Natural Science Scholarship at Trinity College. [illegible] dates are desired to call on the Rector between 8 and [illegible] on Wednesday, October 12. They may obtain further [illegible] tion by application to the Rector, or to Mr. W. L. Bryant, [illegible] Lecturer in Biology at Exeter College.

THE Prospectus of Lectures and Classes for the first session of University College, Nottingham, promises well. There will be both day and evening lectures and classes in Language and Literature (Prof. Symes), Mathematics, Mechanics and Physics (Prof. Fleming), Chemistry (Prof. Clowes), Natural [illegible] (Prof. Blake).

LIGHTNING CONDUCTORS.

Experience, accumulated since the time of Benjamin Franklin, proves conclusively that a Conductor made of Copper of adequate size is the best of all appliances for the protection of every description of building from the destructive effects of lightning.

NEWALL & Co.'S
PATENT
COPPER LIGHTNING CONDUCTOR,

As applied to all kinds of Buildings and Shipping in all parts of the world with unvarying success; is the most Trustworthy, most Effective, and also the Cheapest Conductor ever offered to the Public.
It is simple in its application, no Insulators being required, and it costs only ONE SHILLING per Foot for the standard size, which ensures safety in any storm.

R. S. NEWALL & CO.,
130, STRAND, W.C.; 36, WATERLOO ROAD, LIVERPOOL;
68, ANDERSTON QUAY, GLASGOW.
MANUFACTORY—GATESHEAD-ON-TYNE.

To ASTRONOMERS, OPTICIANS, &c.—

Dr. Hugo Schröder offers for Sale, price 1250 Guineas, the splendid REFRACTING TELESCOPE, equatorially mounted, recently constructed by him, with all the most recent Improvements; now placed for Inspection under a cupola in the Exhibition of Frankfort-on-the-Main.
Particulars:—The Telescope is mounted on a very solid cast-iron pillar, with peculiar arrangements on the axis of Right Ascension, to diminish friction to a minimum. A very uniform movement by clockwork (Foucault's regulator). Diameter of Right Ascension Circle, 17 inches, divided on silver, reading to two seconds. Diameter of two Declination Circles, 23½ inches, likewise divided on silver, reading to 10 seconds.
The Object Glass is made of the celebrated Daguet Glass, 10¼ inches clear aperture, and 13 feet focal length, and gives most satisfactory results, dividing a ¼th second on Terrestrial Objects, and as much as 0".3 on a Celestial Object.
Dr. Schröder has also finished, and will dispose of at a low price, Specula of either silver or glass of beautiful parabolic surface, 7-inch aperture and 72 inches focal length dividing a ½ second. Also several Objectives well centred in their cells, as follows:—4½-inch clear aperture, 62 inches focus. 7, 8, and 12½ inches diameter; the latter having 235 inches focal length.
Apply to Dr. HUGO SCHRÖDER, Oberursel, by Frankfort-on-the-Main; or through Messrs. Ross & Co., 164, New Bond Street, London, W.

SECOND EDITION,
GRIFFIN'S
CHEMICAL HANDICRAFT.
PRICE 4s. 7d. POST FREE.
A CATALOGUE OF CHEMICAL APPARATUS:
ILLUSTRATED, CLASSIFIED, DESCRIPTIVE.
Demy 8vo, 480 pp., Illustrated with 1,600 Woodcuts.
Most Complete and Cheapest List of Apparatus.
JOHN J. GRIFFIN AND SONS, 22, GARRICK STREET, LONDON, W.C.

BEST BLACK INK KNOWN.
DRAPER'S INK (DICHROIC).
DIFFERING FROM ANYTHING ELSE EVER PRODUCED.
Writing becomes a pleasure when this Ink is used. It has been adopted by the principal Banks, Public Offices, and Railway Companies throughout Ireland.

It writes almost instantly Full Black.	Flows easily from the Pen.
Does not corrode Steel Pens.	Blotting-paper may be applied at the moment of writing.
Is cleanly to use, and not liable to Blot.	

Can be obtained in London, through Messrs. BARCLAY & SONS, Farringdon Street; W. EDWARDS, Old Change; F. NEWBERY & SONS, Newgate Street; J. AUSTIN & Co., Duke Street, Liverpool: and to be had of all Stationers.
BEWLEY & DRAPER (Limited), Dublin.

WANTED, Clean Copies of NATURE, No. 472, for November 14, 1878. Address—Office of NATURE, 29, Bedford Street, Strand.

MESSRS. MACMILLAN AND CO.'S
LIST OF BOOKS

TO BE

PUBLISHED DURING OCTOBER, NOVEMBER, & DECEMBER, 1887

The Making of England. By JOHN RICHARD GREEN, M.A., LL.D. With Maps. 8vo.

Life and Letters of John T. Delane, late Editor of the *Times*. By Sir GEORGE W. DASENT, D.C.L. 8vo.

Voyage of the "Vega." By ADOLPH ERIK NORDENSKIÖLD. With Five Steel Portraits, numerous Illustrations, and Maps. 2 vols. Medium 8vo.

Science and Culture, and other Essays. By Professor HUXLEY, F.R.S. Demy 8vo.

Contents.—Science and Culture—Universities Actual and Ideal—Technical Education—Elementary Instruction in Physiology—Joseph Priestley—On the Method of Zadig—On the Border Territory between the Animal and the Vegetable Kingdoms—On certain Errors respecting the Structure of the Heart attributed to Aristotle—On the Hypothesis that Animals are Automatic, and its History—On Sensation and the Unity of Structure of the Sensiferous Organs—Evolution in Biology—The Coming of Age of "The Origin of Species"—The Connection of the Biological Sciences with Medicine.

The Portrait of a Lady. By HENRY JAMES, Junr. 3 vols. Crown 8vo.

A Literary History of the Nineteenth Century. By Mrs. OLIPHANT. 3 vols. 8vo.

Charles Kingsley's Water Babies. A New Edition. With Illustrations by LINLEY SAMBOURNE. Crown 8vo.

The Adventures of Herr Baby. By Mrs. MOLESWORTH, Author of "Carrots," "Cuckoo Clock," &c. With Illustrations by WALTER CRANE. Globe 4to.

Milly and Olly, or a Holiday among the Mountains. Mrs. T. H. WARD. With Illustrations by Mrs. ALMA TADEMA. Globe 8vo.

Pygmalion: a Poem. By THOMAS WOOLNER, R.A. Crown 8vo.

Visions of England. A Series of Lyrical Poems on leading Events and Characters in our History. By FRANCIS TURNER PALGRAVE. Crown 8vo.

Thirty Years, being Poems Old and New. By the Author of "John Halifax, Gentleman." A New Edition. Globe 8vo.

The Adventures of a Little Brownie. By the Author of "John Halifax, Gentleman." New Edition. Globe 8vo. 4*s.* 6*d.*

Macmillan's 2*s.* 6*d.* Juvenile Series.

Our Year. By the Author of "John Halifax, Gentleman."

Little Sunshine's Holiday. By the Author of "John Halifax, Gentleman."

Sermons out of Church. By the Author of "John Halifax, Gentleman." New Edition. Crown 8vo, 6*s.*

Golden Treasury Series.

Sir Thomas Browne's Religio Medi Letter to a Friend, &c., and Christian Morals. W. A. GREENHILL, M.D., Oxon. 18mo.

English Men of Letters. MORLEY.

De Quincey. By Professor MASSON.

Charles Lamb. By Rev. ALFRED AINGER.

Bentley. By Professor R. C. JEBB.

The English Citizen. A Series of on his Rights and Responsibilities.

Central Government. By H. D. TRAILL, Fellow of St. John's College, Oxford.

The Electorate and the Legislature. WALPOLE, Author of "The History of 1815."

The Poor Law. By Rev. T. W. FOWLE.

Bolingbroke as a Political Reformer Being the Members' Prize Essay at Cambridge J. K. STEPHEN, Scholar of King's College, Cambridge.

The Privy Council. By A. V. DICEY, 8vo.

Origines Celticæ. By Dr. GUEST. 8vo.

Physics of the Earth's Crust. By FISHER, M.A., F.G.S., Rector of Harlton.

Macmillan's Foreign School Classics Edited by G. EUGÈNE-FASNACHT. 18mo.

Corneille.—Le Cid. Edited by G. E. FASNACHT.

Molière.—Les Femmes Savantes. Edited by G. FASNACHT.

Subject and Neighbour Lands of Venice By E. A. FREEMAN, D.C.L., LL.D. volume to "Historical and Architectural Illustrations. Crown 8vo.

Practical Politics. Published under the of the National Federation.

Contents:—The Tenant Farmer; Land Law by JAMES HOWARD, M.P. Foreign Policy by HON. M. E. GRANT DUFF. Freedom of SHAW LEFEVRE, M.P. British Colonial DAVID WEDDERBURN, M.P. Demy 8vo.

Lay Sermons. By Professor BLACKIE. Crown 8vo.

MACMILLAN AND CO., BEDFORD STREET, COVENT GARDEN, W.C.

Digitized by Google

MACMILLAN & CO.'S ANNOUNCEMENTS—(*Continued.*)

New Book by the Author of "Ecce Homo."

Natural Religion. 8vo.

International Trade, and the Relation between Exports and Imports. By Sir JOHN B. PHEAR. Crown 8vo.

Milton's Poetical Works. Edited, with Introduction, Notes, and Memoir, by Prof. MASSON. 3 vols. Fcap. 8vo.

Savonarola. A Drama by ALFRED AUSTIN. Crown 8vo.

Duntzer's Life of Goethe. Translated by T. W. LISTER. With Illustrations. 2 vols. Crown 8vo.

Duntzer's Life of Schiller. Translated by P. E. PINKERTON. With Illustrations. 2 vols. Crown 8vo.

The Shakespeare Phrase Book. By JOHN BARTLETT, Author of "Familiar Quotations." Globe 8vo.

Synnövé Solbakken. Translated from the Russian of BJORNSTJERNE BJÖRNSON by JULIE SUTTER. Crown 8vo.

Macmillan's Popular 6s. Novels. New volumes.

My Mother and I. By the Author of "John Halifax, Gentleman." Crown 8vo.

By the Author of "Hogan, M.P."

Hogan, M.P. New and Cheaper Edition. Crown 8vo.

The Honourable Miss Ferrard. New and Cheaper Edition. Crown 8vo.

Flitters, Tatters, and the Counsellor, and other Sketches. New Edition. Crown 8vo.

By the Author of "The Heir of Redclyffe."

Magnum Bonum. Illustrated.

Love and Life. Illustrated.

A Course of Instruction in Zootomy (Vertebrata). By T. JEFFREY PARKER, B.Sc., Lond., Professor of Biology in the University of Otago. Crown 8vo.

Elementary Lessons in the Science of Agricultural Practice. By Prof. H. TANNER. Fcap. 8vo.

Butler's Hudibras. Edited by ALFRED MILNES, M.A. Fcap. 8vo.

Classical Writers. Edited by J. R. GREEN, M.A., LL.D.

Demosthenes. By S. H. BUTCHER, Fellow of University College, Oxford. Fcap. 8vo.

Classical Works:

Lysias—Select Orations. Edited by E. S. SHUCKBURGH, M.A., Assistant Master at Eton College. [*Classical Series.*

Plutarch—Lives of Themistocles and Pericles. Edited by Rev. H. A. HOLDEN, LL.D., Head Master of the Grammar School, Ipswich. Editor of "Aristophanes," &c. [*Classical Series.*

A School Greek Grammar. By Professor W. W. GOODWIN. Crown 8vo.

Exercises in Latin Syntax and Idiom. Arranged with Reference to Roby's School Latin Grammar. By E. B. ENGLAND, M.A., Assistant Lecturer in Latin at the Owens College, Manchester. Crown 8vo.

Key to Second Steps to Greek Prose Composition. By Rev. BLOMFIELD JACKSON, M.A.

The Globe Readers. Adapted to the English and Scotch Codes. Compiled and Edited by ALEXANDER F. MURISON, M.A., Author of "First Work in English," &c. Illustrated. Globe 8vo.

Kant's Critique of Pure Reason. Translated by Professor MAX MÜLLER, with an Introduction by Professor NOIRÉ. 2 vols. 8vo.

General View of the Criminal Law of England. By Sir J. F. STEPHEN, K.C.S.I., and Judge of the High Court of Justice, Queen's Bench Division. New Edition. 2 vols. 8vo.

Mathematical Papers. By the late W. K. CLIFFORD, M.A., F.R.S., Professor of Applied Mathematics and Mechanics at University College, London. Demy 8vo.

The Principles of Political Economy. By H. SIDGWICK, M.A., Prælector in Moral and Political Philosophy in Trinity College, Cambridge, and formerly Fellow of Trinity College, Cambridge. 8vo.

Text-Book of Geology. By ARCHIBALD GEIKIE, F.R.S., Professor of Geology, &c., in the University of Edinburgh. With Illustrations. Medium 8vo.

Further Steps in the Principles of Agri- culture. By Professor TANNER. Globe 8vo.

The Organic Method of Studying Lan- guages. By G. EUGÈNE FASNACHT, Author of "Macmillan's Progressive French Course," Editor of "Macmillan's Foreign School Classics," &c. Extra fcap. 8vo.

Elementary Trigonometry. By Rev. J. B. LOCK, M.A., late Fellow of Caius College, Cambridge; Assistant Master in Eton College. With Diagrams. Extra fcap. 8vo.

Geometrical Exercises for Beginners. By SAMUEL CONSTABLE. Trinity College, Dublin. Crown 8vo.

Electricity and Magnetism. By Professor SILVANUS THOMPSON. Illustrated. Fcap. 8vo.

MACMILLAN AND CO., BEDFORD STREET, COVENT GARDEN, W.C.

NORTH BRITISH AGRICULTURIST

is the only Agricultural Journal in Scotland, and circulates extensively amongst Landed Proprietors, Factors, Farmers, Farm-bailiffs, and others interested in the management of landed property throughout Scotland and the Northern Counties of England.

The AGRICULTURIST has also a very considerable circulation on the Continent of Europe, America, Australia, and the Colonies.

The AGRICULTURIST is published every Wednesday afternoon in time for the evening mails, and contains Reports of all the principal British and Irish Markets of the week, besides Telegraphic Reports of those held on the day of publication.

The Veterinary Department is edited by one of the leading Veterinarians in the country, and is invaluable to the breeder and feeder as a guide to the rearing of animals, and their treatment when labouring under disease.

Full Reports are given of the Meetings of the Royal Agricultural Society of England, the Royal Agricultural Society of Ireland, the Highland and Agricultural Society of Scotland, the Scottish Chamber of Agriculture, and all the principal Agricultural Associations throughout Great Britain and Ireland.

For Advertisers addressing themselves to Farmers a better medium does not exist.

THE ZOOLOGIST:

A MONTHLY MAGAZINE OF NATURAL HISTORY.

Third Series. Edited by J. E. HARTING, F.L.S., Member of the British Ornithologists' Union: contains—

Original articles by well-known naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds; occurrence of rare birds; distribution and migration of British fresh-water fish; new or rare marine fish; local aquaria; British reptiles; British land and fresh-water mollusca, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts.

JOHN VAN VOORST, 1, Paternoster Row.

A DICTIONARY OF MUSIC AND MUSICIANS.

BY EMINENT WRITERS, ENGLISH AND FOREIGN,

EDITED BY GEORGE GROVE, D.C.L.

Vols. I. and II.—Price 21s. each.

Vol. I. A to IMPROMPTU. Vol. II. IMPROPERIA to PLAIN SONG.

Demy 8vo, cloth, with Illustrations in Music Type and Woodcut. Also published in Quarterly Parts. Parts I. to XIV. now ready, price 3s. 6d. each. Cloth Cases for binding Vols. I. and II., price 1s. each.

TO BE COMPLETED IN THREE VOLUMES.

"Dr. Grove's Dictionary will be a boon to every intelligent lover of music."—*Saturday Review.*

"What is modestly called a 'Dictionary' might have fairly been entitled an 'Encyclopædia,' for the editor has included in his scheme everything that belongs to music, or is allied, or is even distantly related to it. It would be a great mistake to regard this work as useful only for the purposes of reference. It is a collection of interesting and valuable articles on all kinds of musical subjects, which amateurs, who take a genuine interest in the art they profess to love, will read from beginning to end."—*Daily News.*

"We now take leave of this 'Dictionary,' recommending it heartily to our readers as full of instruction and amusement."—*The Times.*

"What will strike the reader first of all, perhaps, is the fulness and completeness of the information collected."—*Examiner.*

"As a complete account of the biographical as well as technical materials relating to the art of music and its history, Mr. Grove's Dictionary is without precedent in England."—*Quarterly Review.*

"The work, when complete, will supply a want which has long been felt by amateurs and professors of the art in this country."—*Illustrated London News.*

"This work promises to be for music what the best encyclopædias are to general literature and science."—*Guardian.*

"The excellence of the dictionary becomes more and more conspicuous as the work goes on."—*Daily Tribune* (New York).

THE STRUGGLE OF PARTS IN THE ORGANISM

Der Kampf der Theile im Organismus: ein Beitrag zur Vervollständigung der mechanischen Zweckmässigkeitslehre. Von Dr. Wilhelm Roux, Privatdocent und Assistent am Anatomischen Institut zu Breslau. (Leipzig: Wilhelm Engelmann, 1881.)

SINCE the first dawn of methodical inquiry one of the largest and most important problems that has always been presented to scientific thought is the explanation of the endless number and complex variety of those apparently purposive adaptations of structures to functions which are everywhere to be met with in organic nature. Until within the last few years the solution of this problem was all but universally sought in the hypothesis of a designing mind, and as no other cause had been suggested as adequate to produce such a multitude of seemingly teleological effects, it became a habit of philosophical thinking to regard these effects as evidences of a creating intelligence. And although the scientific instincts of an individual here and there pointed towards the belief that in some unaccountable manner the facts were due to physical as distinguished from metaphysical causes, the scientific instincts which pointed in this direction were unable to justify themselves on grounds of reason, inasmuch as they were unable to suggest any non-mental principle which could reasonably be taken to explain a class of phenomena bearing so suggestively the appearance of a mental origin. The tide of thought in this matter therefore rose without interruption or perceptible hindrance in the direction of supernaturalism, until it attained its highest level in the "Argument from Design" as elaborated by the natural theologians of the past generation. Then with a suddenness only less surprising than its completeness the end came; the fountains of this great deep were broken up by the power of one man, and never in the history of thought has a change been effected of a comparable magnitude or importance.

But although the theory of natural selection as conceived and elaborated by Mr. Darwin so completely subverted the foundations of what may be termed a scientific teleology, it soon became apparent that natural selection alone was not adequate to explain all the facts of adaptation that are met with in organic nature. Not to enter upon the question, which we can only hope that future generations may be able to answer, as to how far natural selection alone, or unassisted by any other principle, is competent to produce changes of specific type—how far, in other words, we are to attribute the evolution of species to the uncompounded operation of the survival of the fittest, and how far to the probable operation of other and unknown factors—not to enter upon this question, it is enough to observe that many cases of adaptation which occur in the parts of individual organisms cannot possibly be explained by the theory of natural selection as this is applied to explain cases of adaptation which are presented by specific types. Thus, to take the most simple illustration, the effects of use and of disuse in increasing or diminishing the functional utility of an organ in obvious adaptation to the requirements of the individual organism—these effects clearly cannot be attributed to survival of the fittest organisms. Similarly in the morbid processes of disease there is frequently observed "an effort of nature" to throw off the affected part, or otherwise to effect a spontaneous cure. These and other considerations of the same kind have led all the more thoughtful evolutionists—including Mr. Darwin himself—to conclude that over and above the great principle of natural selection, operating from without the organism and therefore called by Mr. Herbert Spencer "indirect equilibration," there must be other principles of an adaptive character at work within the organism itself, and therefore collectively called by Mr. Spencer the principles of "direct equilibration." And it is evident that one of the most important problems now presented to evolutionists is that of ascertaining what are these principles of direct equilibration. The work before us is an interesting effort in this direction.

The idea which Dr. Roux elaborates at much length is that the principle of the struggle for existence and consequent survival of the fittest is in active operation, not only as between individuals of the same or different species, but also between the constituent parts of the same individual. As all the parts of an organism receive their nourishment from a common and limited supply, there necessarily arises among them a competition for food, so that, for instance, in any cellular structure the most vigorous cells will survive by starving out the less vigorous, just as is the case with organisms living in an area of limited food-supply. Also, and especially after the period of full growth of the organism has been attained, the mutual pressure exerted by neighbouring cells must give rise to a further competition—a struggle for room or space wherein to develop—and here again it will be the most favoured elements that will be successful in attaining a vigorous maturity. In these and in several other minor respects which we need not wait to mention, Dr. Roux maintains that all the organs, cells, and even molecular groupings of an organism are so situated as to be constantly under the evolutionary influence of the struggle for existence. If such is granted to be the case, the author proceeds to show how a foundation is supplied for explaining all or many cases of "direct equilibration," or, as he terms it, "capacity of functional adaptation." For this capacity amounts merely to an increase or diminution of the functional power of a part under the influence of an increase or diminution of stimulus, using the latter term in its most comprehensive signification as including any change of conditions acting from without. (This, at least, seems to be the sense in which Dr. Roux uses the term, as he applies it indifferently to an excitation of nerve or muscle, increase of traction upon a bone, blood-pressure in an artery, &c.) But if a stimulus means a change of conditions, it means, when frequently repeated, a change of the physiological environment of the structure affected, and therefore, if the constituent parts of this structure are subject among themselves to a keen struggle for existence, those parts which are best adapted to the change will survive, while the others will succumb, with the ultimate effect of altering the form or function of the structure so as to meet the new circumstances of stimulation.

Such in the most general terms is the doctrine advocated in "Der Kampf der Theile im Organismus." Perhaps the most striking feature in the detailed exposition which the author gives of the doctrine is his ignorance of the fact that the doctrine is not original. His work is pervaded by expressions of the importance which he attaches to his idea as that of a new light shining in a dark place, and he is surprised that in the domain of physiology the thoughts of Darwin should not have been earlier applied. But in this country, at all events, the idea is far from being a novel one. Not to mention writers of less repute, Mr. Spencer has meditated deeply upon the causes of "direct equilibration," and his works are over-charged with analogies drawn between the organism physiological and the organism social—analogies which include the struggle for existence and survival of the fittest in all their ramifications. Nevertheless, although Dr. Roux seems strangely ignorant of the philosophy of evolution as taught by Mr. Spencer, his work is of value in pursuing this branch of the subject into greater detail, and with more extensive knowledge of physiology, than has been hitherto done. The topic is a deeply interesting one, and we therefore welcome this attempt at its elucidation. We must, however, observe that Dr. Roux, in the ardour of speculation, is too prone to endow a "muss sein" with the value of an inductive verification; and we must emphatically express our dissent from him wherever he appears to insinuate that the doctrine of natural selection in the domain of physiology has evidence in its favour at all comparable with that which belongs to it in the domain of zoology and botany.

GEORGE J. ROMANES

OUR BOOK SHELF

Pflanzenphysiologie: ein Handbuch des Stoffwechsels und Kraftwechsels in der Pflanze. Von Dr. W. Pfeffer, Professor an der Universität Tübingen. Band I. "Stoffwechsel." (Leipzig: Engelmann, 1881.)

IN treating of the Physiology of Plants, Prof. Pfeffer very naturally divides his subject into two parts, the first being "Stoffwechsel," or metabolism, the second the concomitant "Kraftwechsel," that is, the conversions of latent into kinetic energy and *vice versâ* which are involved in the metabolic processes. The volume now before us treats of the "Stoffwechsel," and it does so in a very thorough and satisfactory manner. In the first place there is evidence in the work of a very complete acquaintance with the extensive literature of the subject, and further, of a critical power of recognising and bringing into prominence those observations which are worthy of being incorporated in the canon of physiological knowledge. The general treatment, too, of the subject is clear and logical, though it suffers from a fault which is not uncommon with German authors, namely this, that the main line of thought becomes here and there obscured by the cloud of detail with which it is enveloped. Still the book is a mine of information for original workers, and a trustworthy guide for advanced students. It is not too much to say that it is the best work in existence on the subject. If the second volume is as good as the first, Prof. Pfeffer will indeed have to be congratulated.

SYDNEY H. VINES

The Norwegian North Atlantic Expedition, 1876-1878. III. Zoology. (Christiania, 1881.)

PART III. of the account of the animals obtained during the above expedition is by the well-known naturalists, D. C. Danielssen and J. Koren, and treats of the group of the Gephyrea. It is illustrated by six plates and has also Of the ten genera and the sixteen species collected during the expedition four of the genera and seven of the species prove to have been undescribed, and a new family is formed for the remarkable new genus *Epibolus*. This genus differs in many respects from any known genus of the Gephyrea; most notably as by reason of the unsured opening through which the sea water gains access to the perivisceral cavity. The analogue of this respiratory fissure is probably not to be found in the class, but the general organisation of this new form is *still truly Gephyrean*. Unfortunately but two examples of this interesting form were dredged up, and even these were not well preserved. They were found in sandy clay at a depth of 870 fathoms in the cold area. In concluding the memoir the authors remark that the two groups into which the class Gephyrea is subdivided, viz. *G. inermia* and *G. armata*, can hardly be regarded as satisfactory. Of several new forms which they describe, and which by reason of their anomalous structure they refer to the second subdivision, none are furnished with the armature on which that subdivision is based. Had therefore the systematic classification been rigorously applied, these would have been referred to the first subdivision, one with which they have but little common, compared to the striking resemblance they bear to those forms comprised in the other. A list of all the species met with and their principal synonyms is appended.

A Manual of Injurious Insects, with Methods of Prevention and Remedy for their Attacks to Field Crops, Forest Trees, and Fruits, and with Short Introduction to Entomology. By Eleanor A. Ormerod, F.R.H.S. Pp. 1-323. 8vo. (London: W. Sonnenschein and Allen; Edinburgh: J. Menzies and Co., 1881.)

THE authoress of this book is well known as an enthusiast in the department of Economic Entomology, and may thoroughly be congratulated upon having produced a work that cannot fail in many ways to be useful to the class of readers for whose instruction and profit it is intended. In many respects it is based upon Curtis's familiar (but somewhat obsolete) "Farm Insects," and many of the usually excellent illustrations are counterparts of those that appeared in that work; many others have originally from the faithful pencil of Prof. Westwood in both cases the old volumes of the *Gardeners' Chronicle* have furnished contributions; a few are from new sources. As in Curtis's work the subject is dealt with according to the plants attacked, not according to the attacking insects, a plan to be much commended in such a work. In each case a short description of the insect and of its methods of attack precede the considerations of Prevention and Remedies. Naturally much is compiled from previous writers; much information given is the result of records obtained from the many willing assistants of the authoress; much is original from *her own* observations. It is not our duty to enter into an examination of the suggested "remedies"; we vastly prefer to look with more favour upon the means of prevention, and are glad to see that generally sound advice in the way of selection cultivation is given throughout. Nor are the meteorological conditions overlooked: we can modify many things —we cannot rule the elements; and in very bad seasons we fear our farmers and gardeners must be content to "pocket the loss" occasioned by insect ravages on crops the constitutions of which have been already much tried by atmospheric conditions. In a few cases subjects appear to have been introduced for the sake of effect. For instance, we doubt if any farmer in the kingdom is one penny the worse for the occasional presence in his potato fields of the larva of the Death's Head Moth; on the other hand many bee-keepers could tell a different tale from the ravages of the moth itself in their hives. The Colorado beetle, of course, has "honourable mention"

Digitized by Google

but we are rather sorry to find the authoress enthusiastic at the passing of the "Injurious Insects" Act of Parliament, which we prefer to consider the outcome of a scare furthered by speculators. All we can say for the "Introduction to Entomology" is that it will possibly serve to give the class for whom it is intended sounder ideas on the subject than generally prevail with them; the Glossary at the end is too short to be of much service.

Zinn: eine geologisch-montanistisch-historische Monographie. Von E. Reyer. 8vo. (Berlin: Reimer, 1881.)

IN this monograph, as is indicated by the agglutinative adjective on the title-page, the author has collected the results of his studies on the technological history of the metal tin under the threefold head of geology, mining, and history; or rather the reader may do so for himself from the material which is presented in an abrupt fashion without either preface or index. The first part of the volume is devoted to descriptions of the tin-producing districts of Saxony and Bohemia, the geological features of each district being first considered, then its history as derived from the local archives and notices in published chronicles, the whole of the facts concerning production being summed up in a chronicle of tin mining in Bohemia and Saxony, with tabular statements and diagrams of the production from the earliest period for which records are obtainable, about the year 1400, down to the present time. From these we gather that the total production of both countries, which was about 100 tons in the year 1400, reached in 1500 a maximum of about 1000 tons, since which time it has steadily declined, the produce at intervals of fifty years varying from 75 to 125 tons annually. At the present time the production is practically confined to Altenberg in Saxony, where about 50 tons are obtained from the treatment of a staminiferous granite containing about 8 lbs. of tin ore per ton. In subsequent sections of the volume the productions of Cornwall, Banca, and Australia are treated in a similar manner; a descriptive sketch of the geology of each locality being given in each case, followed by a chronicle of events and prices. These being mainly compiled from well-known sources, such as De la Bêche's "Cornwall and Devon," Von Diest's "Banca," the reports issued by the Australian and Tasmanian Colonial Governments, &c., present less of novelty than the first part, which contains much original matter derived from the author's own investigations; but the skilful manner in which the information is presented is likely to render the volume very useful to those interested in the subject. An unnecessary difficulty has been introduced by the adoption of the new-fashioned phonetic system of spelling which has latterly become prevalent in Berlin, and will doubtless prove a puzzle to many readers.

The Progress of Meteor-spectroscopy

IN the profound and eloquent review of the progress of British and other discoveries in science during the last half century given in the Opening Address to the British Association at its recent Jubilee Meeting in York by its President, Sir John Lubbock, I am credited (NATURE, vol. xxiv. p. 409) with some meteor-spectrum observations which, while they certainly unfold some of the most important results arrived at in meteor-spectroscopy since its commencement in the year 1866, yet owe their recognition as scientific discoveries of some material weight and real consequence, to quite a different author.

Although with the first use of a meteor-spectroscope I recognised in the persistent streaks of the August Perseids of that year numerous examples of the yellow-sodium line, yet no proof was furnished by the slender spectroscopic power employed, of the existence in the meteor-streaks of any other substance. It was by a Hungarian astronomer, von Konkoly, that the presence of "lithium, potassium, and other substances" in the streaks of shooting-stars was afterwards discovered; and of some of these substances Herr von Konkoly obtained such repeated and well-verified observations, that the identification of their spectroscopic presence in certain meteor-streaks may be regarded as satisfactorily established.

The instruments made by Mr. Browning for the British Association Meteor-Committee in the year just mentioned were intended to be used in studying the spectra of the November Leonids, whose magnificent display took place as expected, but was of such short duration that nothing of great importance was, unfortunately, elicited as regards their spectra. A more successful trial of the instruments had however been made previously on the 9th–11th of August of the same year,[1] and abundant evidence was then obtained of the existence of two classes of meteor-streaks, both equally persistent, one of them affording a continuous spectrum only, like what hot sparks or train-matter would produce; the other more or less charged with, and sometimes consisting entirely of the yellow sodium-line.

No distinct evidence was obtained, however, in that first year's experimental trials of the occurrence in meteor-streaks of any other elementary spectrum-lines besides the solitary sodium one. The spectra of the nuclei were continuous, the brightest ones showing all the prismatic colours in perfection; and only one or two at the same time allowed some traceable evidence of sodium to be detected in their light. But a few of the green "Leonid" streaks were noticed in November to be, to all appearance, monochromatic, or quite undispersed by vision through the refracting prisms; from which we may at least very probably infer (by later discoveries with the meteor-spectroscope) that the prominent green line of magnesium forms the principal constituent element of their greenish light.

Meteor-spectroscopes of a more efficient kind were afterwards devised and produced by Mr. Browning. But they remained, as far as I am aware, without any successful application until the nights of July 25th and 26, 1873, when the spectra of three streak-leaving shooting-stars were observed through one of them by the enthusiastic astronomer of O'Gyalla, near Komorn in Hungary, Herr von Konkoly.[2] The streaks of the first two meteors seen showed only the sodium-line; but in that of the third, which was an emerald-green meteor, the green spectral line of magnesium (Fraunhofer's solar line *b*) was plainly visible in addition to the yellow sodium-line. The spectra of the nuclei were continuous, only the green region of the spectrum in that of the last meteor being of unusual brightness.

On the morning of the 13th of October in the same year Herr von Konkoly again observed with Browning's meteor-spectroscope the long-enduring streak of a large fireball, which was visible in the north-east at O'Gyalla. It exhibited the yellow sodium-line and the green line of magnesium very finely, besides other spectral lines in the red and green. Examining these latter lines closely with a star-spectroscope attached to an equatorial telescope, Herr von Konkoly succeeded in identifying them by direct comparison with the lines in an electric Geissler-tube of marsh-gas.[3] They were visible in the star-spectroscope for eleven minutes; after which the sodium and magnesium lines still continued to be very brightly observable through the meteor-spectroscope; and the streak faded out of sight in a comet-seeker, at last, twenty-five minutes after it was first observed.

In July and August, 1879,[4] and in August, 1880,[5] Herr von Konkoly observed spectra of the nuclei and streaks of many Perseids and other meteors with the Browning's meteor-spectroscope. The yellow sodium-line was conspicuous in most of the streak-spectra, and adjoining it there were seen in many cases the red line of lithium and another more distant red line supposed to be that of potassium; but the violet line of potassium,

Digitized by Google

probably owing to its relative weakness in comparison with the red one, could not be observed. Green and blue lines of other elements were also noticed, among which the most frequently conspicuous one, next to the yellow sodium-line, was, again, the green line of magnesium.

On August 13, 1879, the nucleus of an emerald-green bolide, as bright as Jupiter, produced a splendid continuous spectrum from red to violet, exhibiting first a bright sodium-line, and immediately afterwards the green magnesium-line also, and some others, supposed to be those of copper, with two faint red lines. A similar bolide on August 9, 1880, showed on the continuous spectrum of its nucleus, besides the sodium-line very bright, those of lithium distinctly, and many metallic lines in the green and blue portions of the spectrum.

This occurrence of carbon, magnesium, and other spectral lines (possibly of iron) in the vapour-streaks of shooting-stars and fireballs, establishes a more certain and unequivocal resemblance between their chemical compositions and those of solid meteorites, than does the exhibition of the sodium-line, which, as Herr von Konkoly observes, may possibly be due to the original presence of saline particles in the air itself. But its extreme brightness in some, and total absence in other meteor-streaks, seems yet rather difficult to account for on that supposition. On the other hand the detection of carbon, while it agrees with the element's occurrence in siderites and carbonaceous aërolites, reminds us also of the abundant proofs which Dr. Huggins and other spectroscopic observers have obtained of the same element's prevalence in comets. And indeed the prolonged luminosity of meteor-streaks, with their complex gaseous spectra proceeding for long courses of time from an exceedingly attenuated atmosphere, is itself a physical riddle whose explanation as a mere question of radiation can scarcely be very different from what is demanded by the phenomenon of self-luminosity in the known gaseous nebulæ and in the envelopes of comets.

Of Dr. Huggins' applications of sidereal spectroscopy to nebulæ and comets, it may be mentioned that the extremely eventful discoveries are not individually named and noticed among the many high encomiums rightly bestowed upon that refined use of the spectroscope, in the opening address. But the results therefrom obtained were yet fully as revolutionising as regards the prevailing theories of those bodies, and of the general plan of construction of the sidereal heavens, as some of the spectroscopic discoveries described in the fifty-years' retrospect were (as is there lucidly related) thoroughly subversive of the formerly existing views of the internal physical condition of the sun.

If I have here ventured to disown, and to disclaim for myself some of the major accomplishments of meteor-spectroscopy by showing them to be the results of later, independent, and much more perfect observations, it is because, in comparison with the very significant amplification which those later observations have effected in the subject, the easy recognition of the presence of sodium in meteor-streaks can only claim to be regarded as a slight and inconsiderable first-adventure in a province of spectrum analysis, the additions and improvements subsequently made in which have been attended with much more remarkable success.

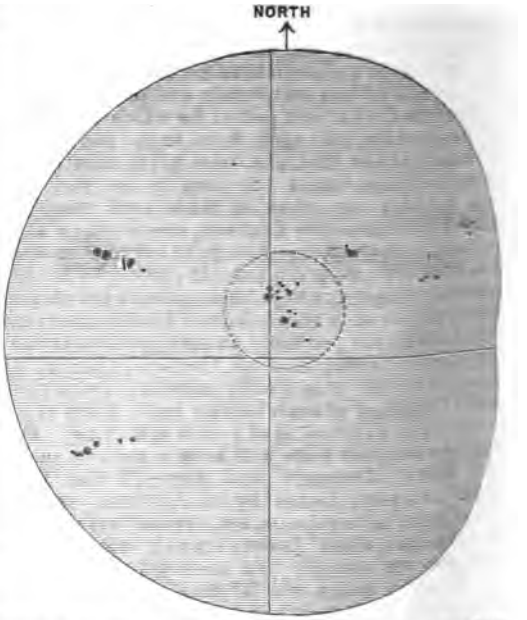
In the wide and accurate survey of the admirable opening discourse, which strays with truly lifelike fidelity over all the broad domains, the well-won fields and gallantly-scaled citadels of modern scientific knowledge, I shall, I trust, be pardoned if, in a matter of very little estimation by itself, I thus attempt to remove and banish from the eulogies of the address a small and unobtrusive and apparently unconscious excrescence of the otherwise harmless and innocent transgression, *magnis componere parva.*

A. S. HERSCHEL

Collingwood, September 12

Sun-Spots

RECORDS concerning phenomena are considerably enhanced in value if they include accurate determinations of the *times* of occurrence. This appears specially applicable to solar phenomena, and particularly to sun-spots, of which there must be many thousands of exact delineations without precise record of the times when the spots first appeared on the visible surface of the sun. No doubt there are several reasons to account for this unavoidable absence of valuable information; amongst others the intense brightness and heat of the sun make it an exceedingly disagreeable object for protracted telescopic inspection; nor ye are we in a position at present to photograph it continuously, r that we are necessarily content to compare photographs taken a intervals of perhaps many hours, and to assume, or at any rate not to dispute, that events of great importance have not occurred in the intervals. This is the more to be regretted because knowledge of solar events is comparatively of little importance unless it helps us to ascertain what influence those events exercise on the earth and its inhabitants; and it is obvious that in comparing solar and terrestrial phenomena the times of occurrence are of essential importance, if only to avoid ascribing an indirect effect to a given cause. It thus follows that even an approximate time of the appearance of sun-spots is not without value. On these grounds, as well as on the score of magnitude, I communicate the following particulars of a recent appearance, or outburst, of sun-spots, which occurred within certain moderate limits of time. I premise briefly that a photoheliograph is in daily use at the Trigonometrical Survey Office, Dehra Doon, India, of which I have executive charge. At present the instrument yields but a 4-inch negative, which is merely a microscopic delineation of a million millions square miles of solar surface; however, as sure



Tracing from sun negative taken at Dehra Observatory, Great Trigonometrical Survey of India. Latitude 30° 19′ 29″ N.; Longitude 5 E. Height above sea 2232 feet, on July 25, 1881, at 4.47 p.m. local apparent time. Spots visible in previous negative taken on the same day at 3.58 p.m. are coloured black; and the new spots which appeared between 4 and 5 p.m. are surrounded by a dotted circle.

as the sun shines, so surely are at least two negatives taken of daily. Interruptions, even in a land of sunshine like this, sometimes occur; notably at the bursting of the monsoon, which occurred here last month (July), when the photographer was compelled to take the sun whenever visible, rather than not take him at all. Under this choice of alternations the first negative (or say N_1) on July 25, 1881, was taken at 3.58 p.m. of local apparent time; it exhibited several sun-spots, as is now usual, and of which therefore little need be said, since solar observers are well aware that the sun has for some months past resumed a state of considerable energy in respect to development of features; the second negative, N_2, was taken at 4.47 p.m. On comparing N_1 and N_2 it was at once seen that in the interval of 49m. a considerable group of spots had appeared in the neighbourhood of the sun's centre. It is exceedingly difficult to exhibit an exact delineation of spots when the negative is on so minute a scale; I however inclose a silver print, as well as a hand-tracing of N_2, from which the position and magnitude of the group, *i.e.* inferred. This new group consists o dividual spot is notably large, but them all, that they exhibit hardly an entirely of well-defined umbra;

Digitized by Google

confined chiefly to two spots, where it is seen only to the south-east; imagine a round, straight hole bored through a stratum of sand sufficiently adhesive for the sides to remain erect for a time, and after this suppose that the sand begins to fall inwards, creating a partial cone around to the south-east side; this is the sort of progress that these two spots convey. As to magnitude, the spots are scattered over an area of some 6000 millions of square miles; while the collective area of the spots themselves is about 630 millions of square miles, or, say, six times the area presented by the earth to the sun. Remembering that of solar change "a little goes a long way," so far as we are concerned, who shall say that changes of this magnitude are inappreciable on the earth, however ineffectual the instruments we can now command may be able to measure them? But was this sudden change inappreciable? that is now the question. Unhappily the sun remained invisible till July 30, when two negatives were taken, *i.e.* after an interval of just five days; so far as solar rotation could effect, the so-called new group of N_2 should have been visible not far from the sun's western edge; but the entire group had vanished, leaving no trace behind. In the interim of five days two new spots had come out; of *one* of these I may add that the umbra is about 200 millions of square miles, and the penumbra some 700 millions, presenting in all a single feature of more than 900 millions of square miles, or say nine times the area exhibited by the earth to a distant spectator. This ends the purport of my letter. But I cannot help adding that I believe the bright solar features or faculæ will eventually prove to be more effective exponents than the dark features or spots; as a matter of fact, faculæ commonly appear in abundance, covering considerable areas and branching out from one another like coral reefs; and it is a mistake to suppose that faculæ exist only in the vicinity of spots; the former may abound where the latter are quite absent, not only in a 4-inch negative, but in a very fair 5-inch equatorial. But I suppose the world will be better informed some day. Meanwhile, surely the sun is worthy of more earnest attention, not only from points of attack already so ably occupied, but from others none the less important, though at present greatly neglected: need I name solar radiation and photography? Physicians are alarmed for the safety of our bodies on detection of even a trifling change in temperature; but what do we know of fluctuations in the source of all terrestrial heat, though it be measurable with an actinometer? Again, land surveys are often made on huge scales; but for the solar survey of 1¼ million millions of square miles, what is our largest delineation, and at how many spots round the world is the required daily record made? If a survey of London pays, depend on it surveys of the sun will pay all nations infinitely better.

India, North-West Provinces, Mussooree, August 5

Proneomenia sluiteri, Hubrecht

IN the report of the Proceedings of the Biological Section of the British Association which appeared in NATURE, vol. xxiv. p. 501, there is a slight mistake in the notice of my friend Dr. Hubrecht's paper on *Proneomenia*. This interesting mollusc is erroneously described as "one of the valuable finds of the *Challenger* Expedition." So far as I am aware, neither *Proneomenia* nor either of the other two genera of the *Solenogastres* (*Neomenia*, *Chætoderma*) was obtained by the *Challenger*. The only two specimens of *Proneomenia* which are known to science as yet were dredged by the Dutch Arctic Expedition of 1878 (or 1879), at depths of 110 and 160 fathoms in the Barents Sea. It was not obtained by the *Wilhelm Barents* in 1880, but we may hope that the dredgings of this season have been more productive, for Dr. Hubrecht informs me that 1881 has been a very bad ice year, and that the *Wilhelm Barents* has not succeeded in penetrating so far north as she has done in previous years. The summer has therefore been devoted to dredging operations, and valuable results may be expected. The zoological results of the Dutch Arctic Expeditions of 1878 and 1879 are being published as supplemental volumes of the *Niederländische Archiv für Zoologie*; and in the second of these, which is now in course of publication, will be found an elaborate memoir by Dr. Hubrecht entitled "*Proneomenia sluiteri*, gen. et sp.n., with Remarks upon the Anatomy and Histology of the Amphineura."

Eton College, September 24 P. HERBERT CARPENTER

Polydonia frondosa

THE Medusa mentioned by Mr. Archer in NATURE, vol. xxiv. p. 307, is undoubtedly *Polydonia frondosa*, Ag., figured in the Contributions to the Natural History of the United States. This Medusa was already known to Pallas, who described alcoholic specimens sent him from the West Indies by Drury. It is stated by Agassiz to be quite common along the Florida Keys. I have myself observed it in great abundance at the Tortugas, in the moat of Fort Jefferson, and in the mud flats to the north of Key West. They occur there in from three to six feet of water, the disk resting upon the bottom, the tentacles turned upwards; the disk pulsates slowly while they are at rest. Their habits when disturbed are well described by Mr. Archer. The young sometimes swim near the surface, and are far more active than larger specimens. When kept in confinement they also creep slowly over the ground by means of their tentacles, or, raising themselves sometimes edgeways against the sides of the dishes, remain stationary for a considerable time. The resemblance of Polydonia when at rest upon the bottom to large Actiniæ with fringed tentacular lobes, such as Phythactis, is very striking. The peculiar habits of Polydonia were noticed by Mertens in a species named by Brandt *P. Mertensii* in 1838; and found at the Carolines. The genus Polydonia was established by Brandt, and not by Agassiz, as is stated by Haeckel in his "System der Medusen." ALEXANDER AGASSIZ

Cambridge, Mass., August 27

Constancy of Insects in Visiting Flowers

MR. A. W. BENNETT'S paper (NATURE, vol. xxiv. p. 501) on the "Constancy of Insects in Visiting Flowers" recalls a note I made at Cromer during the hot weather of last July. On the cliffs west of that town, where flowers were very abundant and of various colours, I carefully watched the movements of a small tortoiseshell butterfly to ascertain what flowers it visited. It was at first busy with bindweed; then it left this for yellow bedstraw (*Galium verum*), returning presently to bindweed. Then it tried a thistle, which detained it some time, after which it shifted to ragwort, and finally revisited bindweed. It seemed equally busy with all these flowers, though so various in form and colour. My tortoiseshell was therefore less constant than Mr. Bennett's, and its visits were successive, there being no interludes on grass, leaf, tree-trunk, or ground.

Brewing in Japan

WILL you permit me to point out an error which has crept into the report of my paper on "Brewing in Japan" in last week's NATURE, p. 468. After mentioning the points in which *Kōji* differs from malt, the report continues:—"Kōji is prepared as follows: a mixture of steamed rice and water is allowed to remain in shallow tubs at a low temperature (0°–5° C.) until quite liquid; it is then heated," and so on. The following alterations will make the account of the Japanese brewing process correct:—"*Saké* (rice-beer) is prepared as follows: a mixture of steamed rice, *kōji*, and water is allowed to remain in shallow tubs at a low temperature (0° – 5° C.) until quite liquid; it is then heated . . . ". Not using malt as we do in our breweries, the Japanese have discovered for themselves a means of rendering the rice-grains diastatic with allowing the embryo to germinate. This is effected by exposing the softened rice-grains to the action of dry steam, by which treatment the starch is gelatinised; when cold the spores of a mould are caused to grow over the surface of the rice, the mycelium being formed at the expense of the starch, and heat being liberated together with the usual products of combustion. The albuminoid matter of the rice, which previously was for the most part insoluble in water, is, after the growth of the mycelium, found to be almost completely soluble, and the solution possesses diastatic properties resembling those of malt extract. The main point in which it differs from the latter is in its superior hydrating power, for, unlike malt-extract, the solution of *kōji* very quickly converts maltose into dextrose. This material (kōji) is then used instead of malt in the mashing process, the sugar formed from the rice-starch under the influence of the dissolved kōji being dextrose, which is further fermented by the accidental introduction from the atmosphere of the germs of a species of yeast. The change induced in the character of the albuminoid matter under the influence of the growing mould is remarkable, and, I think, novel, and the interest of the observations I have made lies in

Digitized by Google

the support they give to the opinion that the diastatic property is connected with the degree of solubility of the albuminoid matter, and in the fact that this may result as well from the growth of an organism foreign to the grain as from the germination of the embryo itself.

Integrating Anemometer

PERMIT me to observe that the integrating anemometer devised by Mr. Shaw and Dr. Wilson, an abstract of whose paper, read before the British Association (Section A), appeared in your issue of September 15 (p. 467), is in principle and in several of its details identical with a machine intended for the mechanical reduction of anemograms of the Kew pattern adopted by the Meteorological Office, a description of which, with drawings, was placed by me in the hands of Mr. R. H. Scott, and by him transmitted to Prof. Stokes in February last. It is however to be noted that there is a fundamental objection to the mode in which such machines deal with the data submitted to them, namely this, that the air does not, in fact, move parallel to itself, as *these* integrators and Lambert's well-known expression assume that it does. In other words, the integrator should concern itself only with those particles of air which *are passing* the anemometer at each instant, *i.e.* with the directions and velocities of successive elements of the wind at a fixed point. Dr. von Oettingen (Wild's "Repertorium für Meteorologie," Band v.) has shown this.

Red Rainbows

THE accounts in NATURE, vol. xxiv. pp. 431, 459, of pink and red rainbows induce me to mention one of a rose colour which was seen in this neighbourhood at sunset yesterday afternoon. Just before setting, the sun shone out with a pale golden glow, but about the north and east there was a general cloudiness, dark inky purple with light masses of cloud floating from north to south, and as the sunset glow lost its golden and assumed a ruddy appearance, these floating clouds took the same colour, the general cloudiness beyond retaining its purple character, and on looking north-east there was the rainbow, or rather the lowest part of the left hand of the bow, almost perpendicular, but inclining, of course, to the east; the general colour was rose, but along the inner side the prismatic colours were plainly seen. It lasted for about five minutes, and was seen by others who were just giving up shooting, about a mile from the house. The clouds in the west soon put on a stormy appearance, and rain began to fall.

Hay Fever

IN Mr. Hannay's letter on Hay Fever (p. 485) two facts are mentioned, viz., that "those who are afflicted with hay fever are so owing to the tenderness of the internal lining of the nose," and that "in Scotland hay fever is practically unknown." By connecting these facts a probable remedy is suggested, viz., the use of snuff. That this habit destroys the natural tenderness of the internal lining of the nose is evident from the insensibility of the snuff-taker to doses that furiously irritate the nostrils that have been differently educated. As Scotchmen generally are either snuff takers themselves or descended from snuff-takers, a direct or hereditary insensibility may explain their immunity from this affliction. Not being one of its victims, I am unable to try the experiment, which should be started a few weeks before the season commences, in order to gradually develop the acquired insensibility.

W. MATTIEU WILLIAMS

Stonebridge Park, Willesden

IN NATURE (vol. xxiv. p. 485) Mr. Hannay remarks that "no remedy yet published will cure hay-fever." Has Mr. Hannay read Dr. Blackley's "Hay Fever" (Baillière, Tindall, and Cox, second edition, 1880)? It will be found that Dr. Blackley has used the treatment mentioned in NATURE, viz. the protection of the mucous membrane of the nose from pollen, with success both on himself and other persons subject to the fever, and Mr. Hannay's experiments offer another proof of the efficiency of this treatment. There is a short article on the subject in the *Lancet* of July 16, p. 82, by Dr. Thorowgood, another by Dr. Blackley in the *Lancet* of August 6, p. 2[illegible] Mr. Hannay's treatment is essentially the same as that practised by Dr. Blackley, though in the latter the [illegible] plugging the entrances to the nasal duct, and the proper air-passages, is avoided, whilst the [illegible] of the eyes is also protected.

September 24

Electric Light in Collieries

THE writer of the article in NATURE, vol. xxiv. p. [illegible] overlooked the long account given in the *Times* of June 14 [illegible] of the visit paid by the Accidents in Mines Commissioners [illegible] Pleasley pit, near Chesterfield, where the first important [illegible] tion of the light was made nearly three months ago. [illegible] should be given to Mr. Swan and to Messrs. Crompton and [illegible] who for more than a year have been experimenting with [illegible] perfecting, the lamps, &c., rather than to those who [illegible] the good fortune to adopt that which the Pleasley trial proved to be so perfect; and, as one who was present with the [illegible] Commissioners, I think it only fair to call your attention [illegible] is probably a slip in your report.

London

THE ORIGIN AND FUNCTIONS OF THE BRITISH ASSOCIATION

MY attention has been called to a pamphlet published by Mr. W. H. Harrison, purporting to contain a correct account of the first founding of the British Association for the Advancement of Science. I am sure that Mr. Harrison, in common with such other readers of NATURE as take an interest in the affair, will be glad to hear my father speak for himself upon a matter which Mr. Harrison, with the amount of information at his disposal, could only treat of as a subject of speculation. The paper which I inclose was addressed to Sir Edward [illegible] Colonel) Sabine; and I think I may claim for it that it is written with much clearness and impartiality. You will perhaps also consider the letter of importance at the moment, as pointing out what was the view taken in the early days of the proper functions of the Association. The wisdom of this view is abundantly evident now that science has been so widely popularised, and that still more of real work remains for the Association beyond the just apportionment of its funds for scientific purposes. In respect to the numerous scientific letters addressed to my father by Buckland, Murchison, Smith, Sedgwick, Scoresby, Humboldt, Wollaston, Davy, Sabine, Faraday, Liebig, De la Bèche, Lyell, and others, I hope some day to cause a selection of them to be produced, in a form which may be of interest, and perhaps of use to the public.

E. W. HARCOURT

Nuneham Park, Abingdon, September 23

Account of the Formation of the British Association by Mr. W. V. Harcourt

"TO COLONEL (AFTERWARDS SIR EDWARD) SABINE

"I HAVE received from the President of the Philosophical Society of Hull (1853) where you know the British Association is about to meet, a memoir which he has put into public circulation descriptive of the nature of that body, its early history, and the specific services rendered to it by individuals.

"The task which Mr. Frost has undertaken is one of a delicate and delicate kind; and I was not surprised to find his description of circumstances with which he had no means of being personally acquainted somewhat inaccurate and defective.

"Mr. Frost informed the public that when in 1831 Sir David Brewster, then Dr., Brewster, made proposals that meetings for promoting science by *réunions* of scientific men similar to those which [illegible] hailed abroad should be held in England and commenced [illegible] York, the country had been duly prepared and predisposed for such co-operation by the severe strictures which [illegible] recently passed on the actual state of science [illegible] on the conduct and character of its scientific [illegible]

Digitized by Google

particular its universities. It would have been better if these strictures, now forgotten, had not been adverted to, especially with reference to the Association. The truth is, they formed the chief difficulty in carrying such a proposal as had been made into effect. It was clear that any attempt at scientific association not headed or joined by many persons who could not but feel aggrieved by the strictures referred to, and who have been since among the chief lights of the institution, would probably have led to results more mischievous than beneficial to science.

"As soon as Dr. Brewster's proposal was made, and before it could be acceded to, I thought it needful to enter into correspondence with numerous individuals thus situated, and finding that, agreeing for the most part in the opinion that such *réunions* would operate for the benefit of science, they lost sight of all personal feelings, and consented to co-operate on certain conditions, I proceeded to draw up the scheme which was ultimately followed.

"It is a mistake to consider this Association as having been formed on any foreign model. My conception of the manner in which a great scientific combination might be effectually worked in England was founded on different principles. No one could be insensible of the advantage to be derived from bringing men of science together to confer and discuss; but even this point I considered it impossible to gain without extending our views considerably further. I did not believe that the great labourers in science would undergo the inconvenience and interruption of travelling to various places to meet one another, as a continuous system, on mere invitation, and for the sole purpose of discussion, and I knew that if such men should absent themselves from the meetings, those meetings would become no better than *foci* of *sciolism* and vanity.

"I therefore proposed to found the Association on the principle of *acquiring funds* to be devoted to the expenses of unremunerative objects of science, of levying such funds from the multitudes of persons who might be expected to feel interested in scientific discussions at populous places, and giving the appropriation of them first to the selection of committee-men attached to the various sections of science, and secondly to the final determination of the whole body of actual scientific labourers at the meeting assembled in general committee.

"To this principle in the constitution of the British Association its success has been mainly due. To this principle we owed, for instance, the unintermitting attendance, to the time of his lamented death, of one of its ablest members, Mr. Baily, under whose direction one of the largest applications of its funds was made.

"These grants of assistance, conjoined with requests to individuals to execute particular tasks for the interests of science, have given the exertions of the Association as a body a direct utility peculiarly its own, tending far beyond the promiscuous discussions of the sections both to advance material objects and to maintain the attendance at its meetings of persons pursuing such objects.

"The wealth, the public spirit, the intelligence, the curiosity, of the great cities of the United Kingdom, offered great encouragement to the financial part of this plan, which by its adoption has enabled the Association to carry out its entire objects not only in regard to liberal grants for scientific objects and in defraying all expenses incidental to its operations and essential to its permanence, but even in maintaining an establishment of its own for experimental research.

"This plan, proposed by me at York, was adopted in all its detail, and my acceptance of the office of general secretary enabled me, with able and zealous co-operation, to work a machine of great magnitude and complexity with a success surpassing my expectations from 1831 to 1837, during which years I was charged with its chief management, and revised all that was printed in its name.

"The cordial reception of the first meeting of the British Association by the city of York, the hospitality of Bishopthorpe, the countenance of the Royal President of the Royal Society, the presence of Lord Fitzwilliam, the aid of Prof. Phillips, the attendance of the distinguished philosopher Brewster, with Brisbane, Robison, Forbes, and Johnston, the attendance from London of Murchison, from Dublin of Provost Lloyd, from Oxford of Daubeny, from Manchester of Dalton, the concurrence of Buckland and Whewell and Conybeare, and many others of known repute, these incidents helped to launch the vessel; of the early history of which, if any one would write accurately of that part of its history, he may record that Brewster first proposed that a craft should be built wherein the united crew of British science might sail, and manfully embarked in it all his high scientific reputation; but for myself I must be allowed to claim that I manned the ship, that I constructed her charts, and piloted the vessel for six years. The labour which I bestowed on this service has since been divided among more capable hands; but none of us could have worked the vessel at all without the constant and invaluable helping hand of the assistant-secretary, Prof. Phillips.

"I am induced to put down on paper and transmit to you, as actual President of the Association, a statement of the real facts, without the least intention, however, of involving either you or any one else in controversy on the subject."

THE INTERNATIONAL EXHIBITION AND CONGRESS OF ELECTRICITY AT PARIS

THE Exhibition must be pronounced a great success. Even those who are well read in electricity are taken by surprise at the display of power presented; and the first favourable impression is strengthened as further examination discloses the immense variety of applications exhibited and the beauty of much of the machinery.

The first thing seen on approaching the Exhibition from the city is the Siemens electrical railway. It is about a quarter of a mile long, with a sharp turn at one place. The carriage is a good-sized tramcar, and presents no special feature to a casual observer, except two wires which travel with it, and connect it by running contacts with two aërial guides suspended on posts like telegraph posts. The prime mover is a steam-engine near the centre of the Exhibition, which drives a dynamo-electric machine. The continuous current which the latter furnishes is led to the aërial guides, and is conducted by the two travelling wires to an electro-magnetic engine beneath the floor of the carriage which drives the wheels. Passengers are conveyed by this tramcar at a small charge between an outdoor station and a station just within the Exhibition.

On entering the building by this tramway one of the most prominent features is the collection of powerful engines which occupies the whole of the space under one of the side galleries. They are for the most part dynamo-machines driven by steam-engines. The dynamos are close to us as we walk down the main passage on this side; the steam-engines, which drive them by belts, are a little further back; the furnaces and boilers are close to the outer wall. Wires are led from the dynamos to electric lamps, some of them close at hand, and others on the opposite side of the building, or overhead.

Every variety of electric lamp is of course to be seen, and their regulators furnish a very interesting study. To illustrate their diversity we may mention that in the Brush system the regulation depends on the variation of resistance in a series of carbon plates as they are more or less strongly pressed together; in the Crompton it depends on the frictional support of a vertical metallic rod by two pieces which pinch it between them, and pinch it more or less strongly according to the strength of the current; while in the Pilsen lamp a spindle-shaped piece of iron is the common core of two electromagnets one above the other, and is drawn up or down as the contact in one or the other prevails. Then again there are the Serrin and other well-known forms of lamp, in which the carbons are caused to approach by means of clockwork, which is regulated by the strength of the current. There is the Jablochkoff candle, in which the two carbons are parallel and separated by plaster of Paris; the Jamin, which is something like the Jablochkoff, with the plaster of Paris removed, and only air between the carbon pencils; the Werdermann, in which a carbon point below bears against a flat block of carbon above (the point being the positive, and the block the negative terminal); the Joel, in which a carbon point below bears against a disk of copper

Digitized by Google

above; and the Soleil, in which the point of contact between the carbon point and the copper is surrounded by chalk or lime, which is rendered incandescent.

Then there are the "incandescent lamps," specially so called, in which a thread of carbon a few inches long is inclosed in a vacuous space where, as there is no oxygen, there will be no combustion, and the carbon does not waste. Swan's light, which is of this class, occupies a very conspicuous place in the Exhibition, and is used for the illumination of the Salle des Séances, in which the meetings of the Congress are held. Edison's two rooms are nightly thronged by visitors, who come to see not only his lights, but his numerous other inventions, which are here exhibited. Lane-Fox's light and Maxim's (which has been stopped by some accident) belong to the same class. No opal or ground glass is necessary with incandescent lights, as they are less dazzling than arc lights. They certainly give very beautiful illumination to a room, and their convenience for lecture-room purposes was well seen on the occasion of an illustrated lecture given by M. Mercadier in the Salle des Séances at the meeting of the Society of Telegraph Engineers on Thursday last. They can be extinguished in a moment and re-lighted in a moment.

The Exhibition is open in the daytime from 10 till 6, and in the evening from 8 till 11. The largest attendance is in the evening, when the lights are in full action. Besides those inside, which make the interior almost like daylight, there are two very powerful lights above the roof, which are furnished with reflectors, and throw beams of light like comets' tails in various directions.

The Congress commenced its sittings on the 15th inst., when an opening address was delivered by M. Cochéry, the official president, and the hours of meeting and other details of organisation were arranged. The foreign members were called upon to elect three vice-presidents to join the three French vice-presidents (all official) who had already been named. After a brief conference Sir William Thomson, Prof. Helmholtz, and Prof. Govi of Naples were proposed and unanimously elected. It was agreed to divide the Congress into three sections, devoted respectively to theoretical electricity, telegraphy with telephony, and miscellaneous applications of electricity, including the electric light; the first section meeting at 9.30 a.m., the second at 2, and the third at 4 p.m. Each section has sat for about two hours daily, an interval of two hours between the first and second being allowed for *déjeuner*.

M. Dumas was elected president of the first section, with Prof. Kirchhoff and Dr. De La Rue as vice-presidents, Prof. Mascart and M. Gérard being secretaries. The discussion of the subject of international electrical units, the choice of which is regarded as the most important work of the Congress, was then begun, and occupied the rest of the sitting. Sir William Thomson introduced the question in a very lucid speech, in which he described the course which had been taken by the British Association, and recommended a substantial adoption of the British Association system. He was followed by Professors Wiedemann and Helmholtz, who favoured the adoption of a mercurial unit of resistance; and a large committee, containing men of both views, was appointed to draw up a Report. This Report was anxiously awaited, and was presented on the 19th inst. It consisted of the following seven recommendations, which had received the unanimous consent of the Committee, and have now been formally adopted by the Congress.

1. The fundamental units for electrical measurements to be the centimetre gramme and second (C.G.S.).

2. The practical units ohm and volt to retain their present definitions, 10^9 for the ohm and 10^8 for the volt.

3. The unit of resistance (ohm) to be represented by a column of mercury of a square millimetre section, at the temperature zero Centigrade.

4. An international commission, to be charged with the duty of determining by new experiments, for practical purposes, the length of the column of mercury, of a square millimetre section, at zero Centigrade, which represents the value of the ohm.

5. The name Ampère to be given to the current produced by a volt in an ohm.

6. The name Coulomb to be given to the quantity of electricity defined by the condition that an Ampère gives one Coulomb per second.

7. The name Farad to be given to the capacity defined by the condition that a coulomb in a farad gives a volt.

It will be observed that the "weber," a unit familiar to British electricians, is not mentioned in these resolutions. The reason, as stated by Prof. Helmholtz to the Congress, is that Weber himself employs a unit of current derived from the millimetre, milligramme, and second, and this unit, which is one-hundredth of the C.G.S. unit, or one-tenth of the weber, as commonly understood by British electricians, is known as "the weber" in Germany.

The reason for adopting a mercurial standard defined by size was explained by Sir William Thomson to be the desire to guard as much as possible against secular change.

It transpired in the discussions which took place in committee that mercurial standards, as actually constructed, are glass tubes which must be refilled with mercury every time they are to be used. The external communications are made by means of platinum wires attached to plates of the same metal, the latter being well amalgamated before use. It is obvious that these operations involve much more labour and risk of error than comparison with a standard coil; and we therefore do not anticipate that recourse will be had to the mercurial standard except on rare occasions. Coils will as heretofore continue to be used for all ordinary measurements of resistance. The international committee which is to make the new determination will be nominated by the governments of the various countries concerned, and independent determinations will doubtless be made by different members of the committee in different laboratories. It will thus be seen what amount of consistency is attainable in such measurements, and whether it is sufficient to render the standard practically accurate. The German authorities assert that accuracy to one part in two thousand can thus be ensured.

THE CAUSE OF COLLIERY EXPLOSIONS

ONE of the most instructive documents ever penned on the subject of the cause of explosions in collieries has recently appeared, in a lately-issued Blue-book, in the form of a Report to the Home Secretary by Prof. Abel, C.B., F.R.S., of Woolwich, who, at the request of the Home Department, conducted a series of experimental researches upon the cause of the terrible disaster at the Seaham Colliery on September 8, 1880. In 1845 Faraday and Lyell first directed attention to the influence exerted by the presence of *coal-dust* in mines upon the magnitude of an explosion of fire-damp. In 1867 and 1875, the subject was further advanced in France by Messieurs Verpilleux and Vital, the latter of whom showed that air charged with fine coal-dust, rich in inflammable material, may explode when there is present a much smaller proportion of true fire-damp than is of itself sufficient to constitute the atmosphere an explosive one. Still more recently Mr. W. Galloway has conducted a valuable series of investigations and experiments, the results of which have been communicated to the Royal Society in three very important memoirs. In the first of these he showed that a certain mixture of air and coal-dust, not itself inflammable, became so when there was also present a much smaller proportion of fire-damp than any Davy lamp could detect. In the second he showed

Digitized by Google

that the return-air from the ventilating shaft of a mine may actually contain enough fire-damp to become inflammable when coal-dust is diffused into it. In the third he concludes that the influence of the coal-dust must not be considered as merely aggravating and increasing the explosion originating with the presence of fire-damp, but that the presence of the dust must be regarded as the one thing which, if a small explosion takes place anywhere, will accumulate and carry forward the force of the explosion with ever-increasing energy into every empty space in the workings, however ramified.

During the current year, experiments have also been made on the subject; at Harton Colliery (Durham) by Mr. Wood and Prof. Marreco, at Broad Oaks Ironworks by the Chesterfield Committee of Engineers, at Garswood Hall Colliery (Wigan), by Mr. Smethurst and the Royal Commission on Accidents in Mines, and lastly at Woolwich by Prof. Abel. The general character of the experiments has been on a plan originally devised by Mr. Galloway: viz. to expose to a flame, or to the flash of a small cannon, a stream of air in a miniature gallery into which any desired percentage of coal-gas or fire-damp was introduced, and into which coal-dust could be diffused by a hopper; arrangements also being made to raise the temperature of the gases, and to increase their velocity at will. The majority of the experimenters believe that in no case does a mixture of air and coal-dust *without fire-damp* explode, although the Chesterfield Committee think they have evidence that flame will travel in dust-laden air without a trace of fire-damp being present. This matter is of great importance, for it has been shown that in flour-mills explosions which have occurred may be traced to the presence of combustible dust in the air.

Prof. Abel had placed in his care thirteen samples of dust, some burnt, others unburnt—collected from different parts of the Seaham mine; which samples were subjected to careful examination in the microscope, and to chemical analysis. They were found to contain from 64·83 to 99·75 per cent. of pure coal-dust, some of them containing ash, grit, and fine sand in various proportions. They were then tested as to their power to aid in producing explosions in an experimental gallery. The gas employed was an explosive pit-gas, of such a quality that a mixture containing only 3·5 per cent. of the gas with air when travelling with a moderate velocity (from 200 to 1000 feet per minute) was ignited by the flame of a naked Davy lamp. In perfectly still air from 4 to 4·5 per cent. of the same gas was necessary to produce the same result. Currents of mixtures of this gas were conveyed into the experimental gallery at a velocity of 600 feet per minute, and at a temperature of 80° F.; a naked Davy lamp, its flame protected from the draught by a small screen, being placed in the gallery at about 12 feet from the place where the dust was supplied to the current. More and more fire-damp was gradually added until explosion took place; that dust being regarded as *most sensitive* which produced explosion with the least percentage of fire-damp. When the relative sensitiveness of the various samples of dust had thus been ascertained, it was found that, of the four which stood head of the list in point of sensitiveness, three headed the list also in point of richness in combustible matter and in point of fineness of texture. But the sample which stood third in point of sensitiveness was not only not the finest, but stood absolutely bottom of the list, in point of richness. It therefore appeared that porosity and mechanical condition are more important than combustibility of the dust in bringing about the ignition of a fully explosive gas. Prof. Abel was led, in consequence, to try whether the ignition of a mixture of air and fire-damp in a low percentage not inflammable of itself by contact with a lamp-flame could be brought about by the agency of a wholly incombustible dust. Accordingly dust such as calcined magnesia, powdered chalk, and slate dust was tried; and it was found that instantaneous explosion was thereby produced in currents of air containing only 3 to 3·5 per cent. of fire-damp. It appears then that *dust of any kind*, as a finely-divided solid, can operate in determining the explosion of an otherwise harmless mixture of gas and air; probably by furnishing, as the particles pass through the flame, successive red-hot nuclei, by which the heat is localised and rendered more intense.

In the special case of dust that is both fine and combustible, as coal-dust may be, it was proved that so small a proportion of fire-damp as 2 per cent. in moderate currents may determine the propagation of a flame by coal-dust. Now, as it is stated on the best authority that the most experienced eye cannot detect the presence of 2 per cent. of fire-damp by its effect on the flame of the ordinary Davy lamp; and as (in spite of all the host of little inventions to detect smaller percentages) the Davy lamp remains the only practical test of the presence or absence of fire-damp in fiery mines, it follows that, in every mine where there is any fire-damp *at all*, the mere dust of the mine constitutes an element of danger of which the risk is simply incalculable. When we add to this that experiments, made by firing such small blasts as eighty *grains* of gunpowder may represent, show that dust may cause the propagation of flame in air-currents containing percentages of fire-damp *far smaller than any* of those mentioned above, it is clear that whatever the risks with Davy lamps may be, they sink into insignificance beside the frightful dangers attending the firing of a shot for purposes of blasting. The practice of blasting the coal cannot be too emphatically condemned. It is at best a lazy and slovenly process of getting the coal, and considering the risks it entails, ought to be stringently and at once put down by legislation.

The practical moral is that, while the Davy lamp is to be regarded more than ever as a necessary of work in the pit, it cannot be regarded in any way as a safeguard of absolute kind against explosion; still less can it be regarded as an indicator of the presence or absence of impending danger, inasmuch as it is absolutely incompetent to detect such feeble percentages of gas as Prof. Abel has shown to be dangerous in the presence of the inevitable dust of the mine.

Science, which gave us the safety-lamp, must therefore be called upon once more to provide efficient substitutes. (1) A new lamp, electric or otherwise, must be devised, which shall be wholly independent of a supply of air from the galleries in which it is used; (2) an indicator must be invented to do what the Davy lamp fails to do, viz. to detect in the workings of the mine the presence of a proportion of fire-damp less than 2 per cent., and to indicate rapidly and accurately its amount. Let us hope that Prof. Abel will crown his labours by giving us such new instruments.

THE LANDSLIP AT ELM

THE Swiss papers contain valuable information as to the landslip which occurred on September 11 in the valley of the Sernft River, in the canton of Glarus. The month of September is notable in Switzerland for landslips. Thus the great landslip of the year 1618, which buried the whole of the town of Plurs in Graubünden, with its 2340 inhabitants, occurred on September 4; and the great downfall of the Rossberg Mountain, which destroyed the village of Goldau, with three other small villages, burying 111 houses and 457 persons, and filled up the Lake of Lowerz, occurred on September 2, 1807. The very heavy rains of the last few weeks have softened the rocks on the slopes of the Plattenberg Mountain, at the foot of which, at a height of 3330 feet, was situated the village of Elm, now almost completely destroyed by the landslip. The clay-slate quarries which were worked

Digitized by Google

upon the same slope have divided the masses of the rocks into large pieces, whilst the frequent earthquakes of the last months have given rise to large crevices in the slates and limestones. Already on September 9 it was perceived that the soil at the quarry was in slow motion, and a house situated immediately below was evacuated. Two days later, between five and six o'clock in the afternoon, it was seen that the forest on the slope of the mountain began to move, the trees being bent like a field of corn during a strong wind; they then rushed down, together with the rocks situated above the quarry, breaking up into thousands of pieces. This formidable stone avalanche reached the village, the trees were bent like straw, and the houses moved by the pressure of air pushed by the landslip. Men and houses were thrown on the opposite side of the valley, smashed against rocks, and buried by the landslip, which, as in the catastrophe of the Rossberg, crossed the valley and rose up-hill on its opposite side. The first landslip destroyed that part of the Elm Commune which is named Unterthal; but a second one followed immediately, destroying the village, and throwing the houses on the opposite side of the valley, one kilometre wide. The picturesque valley of Unterthal is now covered with a mass of mud, earth, and stones, thirty to forty metres thick, on the surface of which are seen blocks of the size of a house. The length of the landslip is about two kilometres, and the opposite side of the valley is covered with stones and blocks on a space of about 100 metres. The Sernft River, which flows in the valley, is barred by the *débris*, and has formed a small lake. The number of persons killed is about 160. Another small landslip occurred on the following day, and the slope of the mountain continues to be in motion. According to a report of Prof. Heim the remnant of the village is also threatened by a landslip, the Risikopf, or Grosskopf, being creviced and undergoing subsidences which render a landslip most probable, not so large, however, as the preceding one.

The *Times* Geneva correspondent writes under date September 19:—"According to the measurements and estimates of Prof. Heim, of Zurich University, who has just visited Elm, the earthslip of yesterday week, though less destructive of human life than the earthslip of Plurs and Goldau, probably exceeds in extent either of those catastrophes, great as they were. The portion of the Tschingel Alp which broke away from the parent mountain measured at its base 400 metres by 350 metres. The length of its projection outwards cannot, of course, now be ascertained. The length of what Prof. Heim calls the *débris* stream is 1500 metres, and varies in breadth from 300 to 400 metres. The distance of the extreme end of the stream from the place whence it broke away is 2000 metres. The extent of the valley bottom, which is tolerably even, covered by *débris* is computed at 570,000 metres, while the entire mass makes a total of 900,000 square metres. From the lower part of the valley to the upper joint of rupture the height is 620 metres. The fall was, therefore, a little over 2000 feet. The lowest estimate of the contents of the slip, according to the admeasurements of the engineers, is 10,000,000 cubic metres. It contains, says the Professor, enough stone to build two cities as large as Zurich, and the population of Zurich is 76,000. Some of the blocks, which are heaped 112 metres higher than the village of Elm, measure 1260 cubic metres, and are estimated to weigh 3300 tons. If the other earthslip, which is regarded as imminent, should take place, all that remains of Elm will be destroyed."

The heavy rains of the last weeks have caused several other landslips in Switzerland and Savoy. In the Upper Singine, in the canton of Freiburg, the soil is in slow motion in the valleys of the Gérine and Singine rivers, and a landslip of some importance has occurred at Planfayon. Another landslip occurred on September 2, close by Bernex village, on the slope of the Dent d'Oche and it is rather remarkable by the circumstance that it occurred in a broad open valley where one never would suppose the possibility of a gliding of rocks.

A further interesting result of the recent heavy rains is that the Lake of Bicune, which is somewhat lower than that of Neuchâtel, is now so full that its water runs into the Lake of Neuchâtel, inundating its shores.

PHENOMENA DEVELOPED BY HELIOSTATIC STAR-DISKS

A HELIOSTAT of the highest class is doubtless beyond the means of ordinary observers, but such an instrument as the one now described is readily obtainable. Three sets of achromatic lenses forming a focal power of forty at ten inches, or a miniaturing power of one-fortieth, are in general sufficient. If formed into a microscopic object-glass, the front is turned towards the sun. The glass then refracts a beautifully small star-disk which, owing to the large angular aperture of the combination, remains steadily in view for several hours. The optical characters of this disk vary considerably with the quality of the lenses; practically a very fine one-quarter by Powell and Lealand produces disks of remarkable beauty and precision. In some cases a plane mirror is conveniently attached to reflect the oblique solar rays.

The instrument thus provides a stationary solar star-disk for continuous observation. No clockwork or machinery is required. The size of the disk is one-fourth of the sine of the solar diameter, or nearly 45-10,000ths of an inch.

A more brilliant form of surpassing effulgence is occasionally employed by a 3-inch lens placed before a right-angled prism. An aërial image of the sun thus produced outshines the electric light. These disks are viewed at a distance of ten feet.

It is proposed to describe first their use in microscopic research, and secondly for telescopic vision.

I. MICROSCOPIC RESEARCH

The Miniature Method.—A strong plate fitting the upper stage of the microscope by means of screws is pierced in the centre by an aperture carrying the "societies" standard screw, into which an objective can be firmly screwed. The stage motions then give readily the necessary adjustments for coincidence of optical axes. This is called the *stage-holder*. All previous methods of fixing the objective in the sub-stage have been abandoned; the necessary steadiness being almost unattainable.

Phenomena of Heliostatic Star-Disks produced by the One-quarter.—Stage-holder armed with an inverted 1-32nd water-immersion. The miniature of the star-disk is now viewed microscopically with a 1-16th immersion. When both of these objectives are adjusted for the most brilliant vision, *distant foliage is distinctly visible*. A flagstaff carrying the Union Jack 180 yards away displays its double cross. The fine lightning-rod surmounting it is distinctly visible. Houses on a hill glisten in the sunshine; but conspicuous above all is the minute solar star-disk blazing with all the glory of a midday Sirius at the open window-sill.

Here the favourite tests for telescopic precision come richly into play. A minute brilliant bead surrounded by the most intensely black ring—the more wonderful as the brilliance seems to heighten its rare and beautiful delicacy and blackness—comes up and plays into expanding coloured rings on each side of the principal focal point. (The delicate beauties of this exquisite phenomenon cannot well be seen without an exceedingly delicate fine focal adjustment.) The focussing wheel (constructed for the lightest contact) is divided into 132 parts; twenty-six give a focal plane the 1000th of an inch deeper or higher.

Digitized by Google

but a tenth part of this, or a change of focus of the 10,000th of an inch, changes the appearance of the magnified star-disk. These changes, so vivid and sudden, produce a lively impression of the minuteness of the wavelets of light which generate these diffractive phenomena.

The diameter of the brilliant disk, as miniatured, is about the 1-20,000th of an inch; the jet black ring in which it appears set, and indeed well set-off, is about 1-100,000th thick. Slight changes in the focus, but especially slight changes in the corrections of the observing and miniaturing glasses, produce a new order of phenomena, full of a significant meaning and practical import. The minimum visible is perpetually forcing itself upon the observer's attention. The lightning-rod (here visible) 6000 inches away, is miniatured 600 times smaller than at 10 inches by the 32nd objective, which then would diminish an object only 320 times. The rod is therefore depicted nearly 200,000 times smaller. It is exactly half an inch in thickness; its size therefore in the miniature is 1-400,000th.

As the evening light faded away a long row of gas-lights reaching half a mile came into view in pretty perspective, the more distant being very slightly out of focus (six divisions). The 32nd objective required to be advanced the 4000th part of an inch for the distant light. In this case the miniature was produced by a Zeiss 1-32nd, and viewed by another 32nd by the same maker. The lowest eye-piece is employed and a shortened eye-tube. A single glance at these microscopic landscapes satisfies the observer at once as to the quality of the instruments of observation. Achromatism is seldom attained without generating a whitish haze, the inevitable accompaniment of residuary spherical aberration. This haze is an invaluable indication.

The haze observed in miniatures examined by high magnifying power is an invaluable indication of spherical residuary aberration. The method gives a cruel test of the optician's art. Its discovery led to the subject coming before the Royal Society and its being embodied in their *Transactions*. When first seen it was exhibited as a strong yellow fog. The announcement of it occasioned the greatest surprise to the distinguished makers of a "very fine" set for the writer. In most cases the higher the angular aperture the denser was seen the fog. The following is quoted: "Mechanical arrangements are shown by diagrams, Figs. 1, 1*a*, plate LII." (*Phil. Tr.*, vol. ii. 1870, p. 592).

"*Experiment I.*—Miniature of a small thermometer, the ivory scale being graduated 24° to the inch. A power of 300 diameters: low eyepiece 'A' and objective of one-eighth focal length (made expressly for Podura testing) was applied to view the miniature formed by a one-sixteenth objective. The following appearances were carefully noted at the time of observation:—

"*Result.*—The sparkle of light on the bulb of the instrument, the graduation, and the mercurial thread within the glass are invisible, obscured by a nebulous yellow fog which no objective adjustments are able to dissipate."

In consequence of this unexpected discovery regarding the quality of a "very fine" one-eighth, it was returned to the opticians, to their surprise, for better compensation. After improvements a very slight nebulous yellow cloud now only remained.

A new fact now came up. A *miniature* formed by an imperfectly corrected glass is comparatively free from the aberration shown by the same glass used as a microscope. Thus, viewed by a good glass, the miniature of an inferior one bore wonderful magnification by an excellent objective.

In innumerable objects surface markings are shown only: with no perspective and with no foreshadow of deeper structures such objects are opaque. But if transparent, the foreshadow of deeper structures confuses the appearance of surface; strange eidola are generated difficult of interpretation and dispersion. A series of star-disks in deeper foci intermingle their diffractions into beautiful forms.

The strong fact that these diffractions of a given disk are wholly developed towards the eye of the observer, or wholly developed beyond the true focal plane, according as the correction of the glasses is over-wrought or under-wrought, reveals an infallible clue to many spurious effects. This method therefore more severely tests the observing instrumentation than the miniature.

The following experiment, arising out of the phenomena in course of observation, is quite a microscopic study in itself:—

Experiment.—Miniature of garden view formed by a 1-30th plano-convex lens and examined by a microscope armed with 1-8th giving 400 diameters.

Result.—Landscape dark and hazy. But upon using the same power (400) with a deep eyepiece and a half-inch objective, there started forth an exquisite picture brilliantly lit up. Even the foliage glittering in the sunlight was sharp, clear, and decisive, the details being marvellously displayed. This large increase of light with diminished observing angular aperture is at first sight astonishing.

It is to such causes doubtless that the microscopic world so long disputed whether the markings on diatoms were depressions or elevations. The earlier plates of such objects, as given by Quekett, teem with eidolic varieties of form. It was thought impossible to resolve them, as it was called, without complicated stops, which in fact shut off the unsuspected residuary aberration.

But it is necessary to pass on to the *fundamental circular spectrum* of a minute solar disk. A simple plano-convex lens of half an inch focus is placed on the microscopic stage and made to form a miniature of the prism star in the field of the microscope. If the experiment be properly conducted, forty gorgeously coloured rings may be counted. I have frequently examined these phenomena with a power of 1000 diameters. Above the best focal point is a bright fog; below are seen the glorious diffractions. The sun, as far as it could be made out, was a spurious disk nearly 6-100,000ths of an inch; the first black-ring, the blackest thing I ever beheld, was nearly the 1-50,000th. Each ring beyond appeared exactly of the same breadth—nearly the 1-16,000th.[1]

If now an over-corrected lens were substituted, the diffraction rings ascended and the nebulosity descended: they exactly changed positions as regards focimetry. The conclusion follows that all brilliant objects present diffractions above or below the true focus according as the observing instrument is over- or under-corrected by means of the usual screw collar adjustment.

In this way the same object, especially diatoms, may be made to take several very deceptive forms, because spuriously diffracted. The same is true of all brilliantly illuminated transparent structures.

The intersection of an infinite number of cones of light converging to different points of the axis here produces the well-known interference extinction of undulation evolving precisely-formed rings of darkness. The simple lens, in these observations, develops circular spectra, as being formed by an infinite number of prisms.

An important outcome of this phenomenon is the unerring test (here presented by a simple single convex plane lens) of the highest possible order, as to the *quality*

[1] The contemplation of these phenomena, utterly eclipsing in their brilliant beauty and precision of form the fainter diffraction phenomena described by Sir John Herschel as amongst the most gorgeous in nature, astonishes every beholder. Some little skill is required in gradually toning down the excessive, I might say painful, glories of the appearances—lengthening the eye-tube; glass tinted wedges (a single field-lens of a Hyghenian as eyepiece produced a spectrum apparently twelve inches in diameter, measured with the left eye by rule laid on the stage), or by camera.

Digitized by Google

or inferiority of the observing microscope. Extreme steadiness and a *particularly* delicate fine focussing adjustment are indispensable for successful observations. It is impossible here to detail them.

A plain silvered mirror of the old style must be discarded as a solar reflector; prismatic internal reflexion or reflexion from a metallic surface is indispensable for producing purity of spectra.[1]

But it is when superb objectives are placed as it were eye to eye, that the finest observations can be made (especially when both are used with their noses inserted in the proper immersion fluid for observing landscapes) on distant objects.

The extreme delicacy of the change in focal planes of vision is charmingly illustrated by observing with a good 1-8th the miniature of two brilliant points, the one 200 inches, the other 201 inches away in the same line. If the miniature is formed by a simple lens, theoretically the focal images of these star-disks would be separated by an interval of 2-10,000,000ths of an inch for a 1-10th lens, *perfectly* aplanatic.[2]

These disks, by their rapid change in appearance, give the most exquisite means of determining focal changes in the microscope. Thus for a focal depression of 7-10,000ths of an inch a change took place from *one* pure jet black diffraction-ring round central disk to eleven rings. The rings changed visibly for a focal depression of 100,000th of an inch.

The greatest confusion has existed regarding the terms penetration, definition, and resolution. The study of star disks miniatured by surpassingly well-corrected glasses furnishes the observer with a new order of facts upon which irrefragable conclusions can be founded.

A telescope of very fine quality should have a focus of extreme delicacy. One whose change of focus by 1-10th of an inch produces little or no effect upon the "definition" is contemptible. In the same manner the quality of microscopes may be estimated by the striking effects of a minute focal change. The planes of focal vision, it will be found, vary extremely, their interval varying according to a function of several complex factors.

The prism-heliostat already described is well represented by an Amici prism. Small bulls-eye lenses, laid with the convex surface upwards in the sunshine, present two brilliant images of the sun at a distance of 200 inches. They are of unequal brilliancy. A row of these placed in a line with the axis of the instrument,[3] and somewhat tilted, so that the star-disks may be all seen at once, will develop a series of fine microscopic effects, dependent on the corrections of the systems in use and the immersion-fluid in which the noses of the glasses are inserted (sometimes a piece of adherent glass cover intervening, as the water tends to run off). If a 1-33rd objective be employed to miniature them, and a 1-16th to observe them, extraordinary fine excellence insures a perspective almost as clear as an opera-glass. The minute double stars—which may be brought as close as we like by change of the angle of position of the instrument with the sun's azimuth—produce a variety of diffraction rings, mingling, crossing, and breaking up each other in a manner that could hardly be suspected during the telescopic observation of real double stars. Seldom can a bright landscape be attained without leaving some little outstanding colour. If that be destroyed by changing the glasses or corrections immediately, *all black objects look grey*, and the grey lighter as the colour nearly vanishes. The ... view is charged with a thin greyish-white ... sure indication—as already described—of ... ration. Just within the best focus an exquisite dark-grey bead margined with black ... primary brilliant disk (half its size)—may be ... by close attention and a particularly well-adjusted ... ing apparatus.

In observing these interesting phenomena it ... seen that larger[4] and smaller spurious disks are ... according to the curvatures of the bulls-eyes; but ... is one minimum size; and those, when ... trate diffraction spectra in a brilliantly ...

first intensely black first ring, fainter stars telescopically show smaller disks.

But whilst a close row of spurious disks are seen to coalesce and obliterate themselves if too close, and become continuous as a thick luminous line—the necessary effect of bright diffractions—duller objects devoid of brilliance are seen of amazing minuteness of tracery.

Example.—The rungs or rounds of a ladder resting against a house half a mile off were distinctly seen when miniatured down to 1-1,000,000th of their actual size, *i.e.* considerably less than 1-1,000,000th of an inch. This feat was accomplished by an immersion 1-32nd by Seibert, which diminishes an object 30,000 inches away just about 1,000,000 times. The bane of minute microscopic research is thus seen to essentially consist of a combination of diffraction with the haze of aberration.

A blue glass evidently diminishes the diffraction phenomena; so do neutral tints. This exactly tallies with the shrinking of spurious telescopic disks during haze and sky-clouding. These facts forcibly point out the great advantages of observing in mild light. In further support of this the writer has thus effected several very difficult resolutions—in the "Ultima Thule" of microscopic investigation glare is the prolific parent of many fallacious interpretations.

These studies have encouraged the writer to continue a research into the limits of human microscopic vision. In the case of bright illuminations the limit is evidently reached at once. A minute refracting spherule thus forms a bright focal point which itself exceeds by expansion into a spurious disk, the diameter of the spherule producing it. Down to a certain size a focal image is discernible. A very interesting study is given by the solar star-disks presented by receiving the rays from the heliostat after passing through a beetle's eye placed on the field of view on the stage of the microscope.

FIG. 1.—Taking the objects from left to right, a representation is given of a miniature magnified a thousand times linear and the various appearances of the heliostatic star disks with slight changes of focussing. 1. Large diffraction rings: *fundamental spectrum* given by a plane convex lens ¼ inch focal length placed on stage of microscope. Forty rings have been counted. 2. Optical gauge: various lenses showing spurious disks with minute diffraction rings similar to those on the "bulls-eye" in centre of picture. 3. Intensely clear bright star disk produced by very perfect instrumentation. 4. A cross given by imperfect glasses. 5. Larger expanding rings, the miniature or observing glasses being either under or over-corrected. 6. The finest and clearest spurious disk attainable.

NOTE.—The house on the hill distinctly seen in this case of very finely corrected glasses. A miniature formed by a very fine 1-32nd gives the distant house and window nearly in the same focal plane.

Until the sun shone the window appeared miniatured in each eye. It seems curious to measure the focal length. By measuring the images this was found to be 1-1000th of an inch, giving enormous magnification for ordinary vision.[1] The solar disk, however, appeared spuriously enlarged.

More wonderful diffraction-phenomena are developed by different treatment. A half inch condenser-objective was inserted between the coleopterous eyes and the heliostat—behind or beyond the stage. The solar disks developed then appeared severely beautiful. No such wonderfully sharp black rings are even viewed telescopically. These phenomena are in order of focal classes—

1. Intensely black truly formed rings.
2. Hexagonal black patterns on a brilliant ground.
3. Three such hexagonal rings to each eye-facet.
4. Five such finished off with extremely rich Scotch plaid patterns, highly coloured.

G. W. ROYSTON-PIGOTT

[1] Their focal length was measured by selecting a well-defined object, as a red brick house, carefully measuring micrometrically a given part of it, and then measuring an image of the same thing in a known lens.

If d be the distance of the object from its image, m the size of its miniature, M the size of the object,

$$f = d \times m \div M.$$

A convenient formula for estimating the focal length of a small lens was given by me in the *Phil. Trans.* If it is found to magnify m times at a distance *between object and image* d, and if m be considerable,

$$f = \frac{d}{m+2}, \text{ more accurately } = \frac{d}{m + \frac{1}{m} + 2}.$$

NOTES

THE Delegates of the Clarendon Press will shortly publish an "Elementary Treatise on Electricity," by the late Prof. James Clerk Maxwell, edited by Mr. W. Garnett, formerly Fellow of St. John's College, Cambridge. The book was commenced about seven years ago, but its completion was prevented by the author's other engagements; so that during the last three years of his life very little was added to the work. After his death the first portion of the manuscript, on Statical Electricity, was

Digitized by Google

found in a finished state, as well as some chapters on Current Electricity. The book has been completed so as to cover the subjects included in the first volume of the larger Treatise on Electricity and Magnetism by a selection of some of the simpler articles from the last-mentioned work. As in the larger treatise, the "method of Faraday" has been followed throughout; but no knowledge of the higher mathematics has been assumed, and geometrical methods have been almost everywhere adopted. Very much of the matter contained in the work will, we are informed, be new to readers who had not the advantage of attending Prof. Maxwell's lectures at Cambridge, and the whole book bears indelibly the stamp of Prof. Maxwell's originality. It is as much unlike any other book on electricity as the "Theory of Heat" or "Matter and Motion" is unlike other books on thermodynamics or mechanics. The Clarendon Press likewise have nearly ready for publication a second edition of Prof. Clerk Maxwell's "Treatise on Electricity and Magnetism," edited by Mr. W. D. Niven, Fellow of Trinity College, Cambridge.

WE regret to announce the death, at the age of forty years, of Dr. Gustaf Linnarsson, the able palæontologist to the Swedish Geological Survey; he died, in consequence of a severe attack of disease of the chest, at the house of his brother, in the town of Sköfde. Even when at school he occupied himself with the geology and palæontology of his native province, Westrogothia. He took his degree as M.A. in 1866 with high honours, and was nominated "Docent" in Geology at the University of Upsala. In 1870 he joined the Geological Survey of Sweden as palæontologist, and since that time has worked at the classification of the Cambrian and Silurian rocks of Sweden. He has expounded his views in a numerous series of geological and palæontological papers, which all prove his accuracy and caution in drawing conclusions. The now adopted classification of the oldest Palæozoic rocks of Sweden is chiefly his work. The fossil groups in which he made his researches are the Trilobites and the Graptolites. His premature decease is a heavy loss to science, the more so as he has left behind him several important works unfinished.

THE death, resulting from a fall from a horse, is announced of Frederick Joy Pirani, lecturer on Natural Philosophy and Logic at Melbourne University. Mr. Pirani was born in Birmingham in 1850, but went to Victoria when a boy, and was there educated. He was an accomplished mathematician, and gave promise of future eminence. He was active in the promotion of science in the Colony. Mr. Pirani was an occasional contributor to our pages.

AT the last general assembly of the Swiss Alpine Club Mr. Whymper was elected honorary member, "in recognition of his having contributed, as few other travellers have done, to the exploration and renown of the Alps."

THE introductory lecture for the present Session at University College in the Faculty of Science and Arts will be given by Prof. Bonney, F.R.S., on Tuesday, October 4, at 3 p.m., in the Botanical Theatre. The subject will be "A Chapter in the Life-history of an Old University," or a sketch of the chief changes, educational and social, at Cambridge during about the last hundred years. The lecture is open to the public without tickets.

MESSRS. SAMPSON LOW AND CO. announce the following books for the forthcoming season:—"The Head Hunters of Borneo: Up the Mahakkam and Down the Barita; also Journeyings in Sumatra," by Carl Bock; "Uganda and the Egyptian Soudan: an Account of Travel in Eastern and Equatorial Africa; including a Residence of Two Years at the Court of King Mtesa, and a Description of the Slave Districts of Bahr-el-Ghazel and Darfour. With a new Map of 1200 miles in these Provinces, numerous Illustrations, and Anthropological, Meteorological, and Geographical Notes," by R. W. Felkin, F.R.G.S., and the Rev. C. T. Wilson, M.A. Oxon., F.R.G.S.; "Magyarland: A Narrative of Travels through the Snowy Carpathians, and Great Alföld of the Magyar," by a Fellow of the Carpathian Society (Diploma of 1881), and author of "The Indian Alps"; "Through Siberia": illustrated with about thirty engravings, two route maps, and photograph of the author in fishskin costume of the Gilyaks on the Lower Amur, by Henry Lansdell; "Nordenskjöld's Voyage around Asia and Europe: a Popular Account of the North-East Passage of the *Vega*," by Lieut. A. Hovgaard, of the Royal Danish Navy, a Member of the *Vega* Expedition; "South by East: a Descriptive Record of Four Years of Travel in the Less Known Countries and Islands of the Southern and Eastern Hemispheres, by Walter Coote; "Upolu; or, A Paradise of the Gods: being a Description of the Antiquities of the Chief Island of the Samoan Group, with Remarks on the Topography, Ethnology, and History of the Polynesian Islands in general," by the late Handley Bathurst Sterndale, edited and annotated by his brother.

AMONG Messrs. Macmillan and Co.'s announcements of forthcoming books are the following:—"Voyage of the *Vega*," by Adolf Erik Nordenskjöld (with five steel portraits, numerous illustrations, and maps); "Science and Culture, and other Essays," by Prof. Huxley, F.R.S.; Charles Kingsley's "Water Babies" (a new edition, with illustrations by Linley Sambourne); "Origines Celticæ," by Dr. Guest (with maps); "Physics of the Earth's Crust," by Rev. O. Fisher, M.A., F.G.S.; "A Course of Instruction in Zootomy (Vertebrata)," by T. Jeffrey Parker, B.Sc. Lond., Professor of Biology in the University of Otago; "Elementary Lessons in the Science of Agricultural Practice," by Prof. H. Tanner; "Mathematical Papers," by the late W. K. Clifford, M.A., F.R.S., Professor of Applied Mathematics and Mechanics at University College, London; "Text-Book of Geology," by Archibald Geikie, F.R.S., Professor of Geology, &c., in the University of Edinburgh (with illustrations); "A Treatise on Chemistry," by H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S., Professors of Chemistry in the Victoria University, Owens College, Manchester (with illustrations): Vol. III. "The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry," Part I.; "Further Steps in the Principles of Agriculture," by Prof. Tanner; "The Organic Method of Studying Languages," by G. Eugène-Fasnacht; "Electricity and Magnetism," by Prof. Silvanus P. Thompson (illustrated).

MR. B. SAMUELSON, M.P., F.R.S., the chairman of the Royal Commission on Technical Instruction, has returned from a visit to Berlin, where, through the courtesy of our Ambassador, Lord Ampthill, he has secured the assistance and co-operation of the German authorities in the collection of preliminary information bearing on the subject of the inquiry. He has also made arrangements for the forthcoming visit of the Commissioners to the manufacturing districts of Westphalia. At the first meeting of the Royal Commission it was resolved that among the points to be examined should be the instruction afforded on the Continent to the proprietors and superior managers, the foremen, and the workpeople engaged in industrial pursuits, and that investigation should also be made into the connection between general and technical instruction, and the sources of the funds from which such instruction is defrayed.

THE last field meeting of the year of the Woolhope Naturalists' Field Club, we learn from the *Gardeners' Chronicle*, will be held at Hereford, on Thursday, October 6, for a foray among the funguses. There will be an exhibition of funguses in the museum room at the Free Library, and an evening meeting at

Digitized by Google

be held there on Wednesday, October 5, at 8 p.m., to name and study them. The foray will be made in Stoke Edith Park and grounds, by the kind permission of Lady Emily Foley. A meeting of the members will be held in the Woolhope Club-room at 3.45 to elect the officers for the ensuing year, and to transact the ordinary business of the Club. The dinner will take place at the Green Dragon Hotel at 4.30 p.m., and a *soirée* will be held at the house of Mr. Thomas Cam at 8 p.m., to which he kindly invites all who may be present at the meeting. After dinner, or at the evening meetings, papers will be read on the following subjects:—The progress of mycology, by Dr. Bull; fungus mimics, by M. C. Cooke, M.A., LL.D., &c.; the Herefordshire Carices, by the President of the Club; the fungi of the Dolomites, by Thomas Howse, F.L.S., &c.; the fungi which attack the wheat, by the Rev. John E. Vize, M.A.; the germination of the Uredines, and the relationship of *Æcidium berberidis* to *Puccinia graminis*, by Mr. C. B. Plowright; Protococcus, by the Rev. John E. Vize, M.A.; monstrosities in fungi, by W. Phillips, F.L.S., and a curious and abnormal cellar Polyporus will be shown by Mr. Phillips; two tomato diseases, by C. B. Plowright. The Pomona Committee of the Club have decided to hold an exhibition of apples and pears on Wednesday and Thursday, October 26 and 27, and schedules of the prizes offered may be obtained from the hon. secretaries, Woolhope Club-room, Free Library, Hereford.

ALL who have to consult or translate from French scientific and technical works will welcome Dr. F. J. Wershoven's "Technical Vocabulary, English-French, for Scientific, Technical, and Industrial Students" (Hachette and Co.). The vocabulary is arranged according to subjects, beginning with general notions on matter, and going on to force and motion, gravity, and other subjects in physics, mechanics, and chemistry, and their applications, and giving all the words and phrases in use in regular order. An ample alphabetical index renders the vocabulary easy of consultation. There is also an English-German edition.

MR. A. TREVOR CRISPIN, writing from Hyde End House, Brompton, Reading, sends us the the following information:—He is staying with his brother-in-law, Capt. Johnston, and the other morning, as usual, Capt. Johnston had had a cut fluted tumbler brought to his dressing-room filled with milk warm from the cow; into this a small quantity of rum was put, and the whole left standing. While Capt. Johnston was having his bath there was a loud noise, and on looking round he found the tumbler had parted in two, and there was an interval of four or five inches between the two parts. The fracture commences near the top (and the circumference at the top remains unbroken), at the very line of the level of the milk, the mark of which remained quite distinctly on the glass. This was the second occurrence of a precisely similar nature, the first having taken place about a month ago; but then the fracture took place some minutes after the contents of the glass had been consumed.

WE learn from the *Bulletin* of the Physical Observatory at Tiflis, that on August 24, at 11.18 p.m., there was felt in that town an earthquake which consisted of three shocks, direction from north-east to south-west. The same earthquake was felt at Gori at 11.9, at Kutais at 11.40, the direction being from east to west; at the station Kobi of the military route at 11.27, the direction being north-west to south-east; and at Gomi, a station of the Poti and Tiflis railway, where it lasted for about twenty-five seconds.

AN earthquake shock, very slight in this neighbourhood, but stronger further east, was felt in the basin of the Lake of Geneva on Friday. The earthquake was followed by a violent thunderstorm, which seemed to extend from the Alps to the Jura. Several vessels were wrecked and some lives were lost on the Lake of Brienz. A village in the district of Albula is threatened with a disaster similar to that which has just befallen Elm. The village lies at the foot of the Rothorn, a mountain in which there are several deep fissures, a part of which has been actually in movement for some time. Several engineers have already inspected the locality, and the intervention of the Federal and Cantonal Governments is demanded, in order that, if possible, measures may be taken to avert the impending peril.

A SHOCK of earthquake occurred on September 25 at Elmira, State of New York, followed by a destructive hurricane, which was, however, of short duration. On Thursday last, at noon, further shocks of earthquake alarmed the inhabitants of Orsogna, Lanciano, and Castel Frentano, where a landslip did serious damage.

THE Calendar of the Mason College, Birmingham (which has already attained considerable thickness), for the ensuing session contains a very satisfactory programme of the teaching promised by this institution. The session opens on Tuesday next with two introductory addresses, by Prof. R. H. Smith (Civil and Mechanical Engineering), and Prof. Edward Arber (English Literature).

MR. J. W. SWAN, the *Photographic News* states, has entered into an amicable arrangement with Messrs. Siemens Brothers the well-known electricians—they to employ his lamp, and he t use their apparatus. In company, they are to light up the new theatre in Beaufort Buildings with electricity, three hundred of Mr. Swan's lamps being used on the stage and in the auditorium. At the Paris Electrical Exhibition they are making a fuss over the model of a theatre lit up by electricity; in London we shal have the real thing.

M. FERRY, French Minister of Public Instruction, has authorised the opening at Montpellier of the first national college for the education of females.

THE Jamaica Government are offering great advantages to those who are inclined to embark in the cultivation of Cinchona. Suitable land is offered at a very low rate, and it seems to us that, with proper methods and selection of the right kind of plants, there is room in Jamaica for a limited number of plantations of this kind. In connection with this, Mr. D. Morris has issued a valuable series of "Hints and Suggestions for Raising Cinchona plants from seeds, and establishing Cinchona plantations."

"PROFITABLE and Economical Poultry-Keeping," by Mrs. Eliot James, is a useful little work, published by Ward, Lock, and Co.

WE have received the Reports of the Leicester and Nottingham Literary and Philosophical Societies. The former is divided into various science sections, each of which seems efficient. The Leicester Society is printing a record of its early *Transactions*, part vii. extending from June 1860 to June 1865.

A PROPOSITION has just been set on foot for an exhibition of naval and submarine engineering appliances, which is to be held in the early part of next year at the Agricultural Hall, Islington. It is intended to cover the wide field occupied in the production of machinery and mechanical contrivances employed in, or connected with, the construction and equipment of ships of all classes.

MESSRS. GRAS AND CO. of Madrid announce the publication of a Popular Illustrated Encyclopædia of Science and Art, edited by Mr. F. Gillman, mining engineer. It seems to be modelled on the German Conversations lexicon, though, to judge from the

Digitized by Google

prospectus, the work will be arranged according to subjects, and not alphabetically.

NOWHERE, according to Prof. Porter, President of Queen's College, Belfast, is the vital importance to the nation of technical education more keenly felt than amongst the merchants and manufacturers of Ulster. "Germany" (observes the same authority) "provides buildings, laboratories, and scientific apparatus on the most liberal scale. In France, Belgium, Switzerland, and the United States of America, higher technical education is making rapid strides under the fostering care of the respective Governments, aided by the generous contributions of patriotic citizens. The results of this wise liberality, while enriching those nations, are most seriously affecting the manufacturing interests of this country, and especially of Belfast and Ulster." Prof. Porter considers that in order fully to develop the latent resources of that part of Ireland we must have the means of giving young men a scientific training.

IN the *Bulletin* of the Essex (U.S.) Institute for April, May, and June is a paper by the Rev. G. F. Wright, on the Glacial Phenomena of North America, and their Relation to the question of Man's Antiquity in the Valley of the Delaware.

THE additions to the Zoological Society's Gardens during the past week include two Bonnet Monkeys (*Macacus radiatus*) from India, presented respectively by Mr. J. Thompson and Mr. C. Green; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. W. Thomson; a Banded Ichneumon (*Herpestes fasciatus*) from West Africa, presented by Mr. W. Cubitt; two Common Otters (*Lutra vulgaris*) from Ross-shire, N.B., presented by Mr. H. Mitchell; a Black-crested Eagle (*Lophoaëtus occipitalis*) from Africa, presented by Mr. E. A. Harland; a Brush Turkey (*Talegalla lathami*) from Australia, presented by Capt. F. M. Burke, s.s. *Cheybassa;* a Red-legged Partridge (*Caccabis rufa*), European, presented by Mr. J. E. Clayton; a Common Cuckoo (*Cuculus canorus*), British, presented by Master Alfred Beart; an American Black Bear (*Ursus americanus*) from North America, deposited; four Zebra Waxbills (*Estrelda subflava*) from Africa, purchased; a Collared Fruit Bat (*Cynonycteris collaris*), three Undulated Grass Parrakeets (*Melopsittacus undulatus*), bred in the Gardens. The additions to the Insectarium include larvæ of the Comma Butterfly (*Vanessa C. album*), scarce Swallow-tail Butterfly (*Papilio podalirius*), and Privet Hawk-Moth (*Sphinx ligustri*). Also imagos of *Ranatra linearis*, and a specimen of *Attacus atlas* reared from larvæ hatched in the House.

OUR ASTRONOMICAL COLUMN

THE SATELLITES OF MARS.—The approaching opposition of this planet does not hold out much probability of satisfactory observations of the satellites except with the larger instruments, though in European latitudes the meridian altitude, which is an element in the case, will be considerable. Taking Prof. Asaph Hall's unit for brightness in 1877, viz. that on October 1, when the outer satellite was seen with the 9·6-inch equatorial of the Naval Observatory, Washington, we find the maximum brightness at the next opposition will be represented by 0·4, which is a less value than corresponds to the last date of observation with the 26-inch refractor at the same observatory. It may be remembered that Mr. Common observed *Deimos* on the morning of September 2, 1879, without much difficulty with his reflector of 3-feet aperture, when the degree of brightness in terms of Prof. Hall's unit was 0·50; at the last Washington observation in 1879 it was 0·52. The earth being only about 10° from the line of nodes of the satellites' orbits at the opposition in December next, their apparent paths are reduced almost to straight lines. The longitude of the ascending node of *Deimos* is 88°.

THE SATELLITES OF SATURN.—Mr. Marth has again prepared ephemerides of the five inner satellites of Saturn, which have been published in the *Astronomische Nachrichten*; he appends differences of right ascension between the outer satellite, *Japetus*, and the centre of Saturn, but he does not mak *Hyperion*. Preceding the ephemerides are auxiliary quantit for every fifth noon at Greenwich, by means of which the po tions of the five inner satellites may be determined for any ti required from the formulæ—

$$s \sin (p - P) = a \sin (l - L)$$
$$s \cos (p - P) = b \cos (l - L).$$

Here p is the angle of position with reference to the plan centre, and s the distance therefrom; the values of $(l-L)$ a of the semi-axis a and b are tabulated for each satellite, as we as the angle P, which is applicable to all five. The process simple enough to any one initiated in such calculations, but there may be observers to whom they are unfamiliar, an exam may not be out of place here.

Let it be required to determine from Mr. Marth's tables th angle of position and distance of *Mimas*, at Greenwich mi night, on October 1. We have then—

$(l-L)$ Oct. 1d. 0h. ... 287°·60	$\log a$ ... ... +1·48
Motion in 12h. ... ... 191°·04	$\sin (l-L)$ ... ... +9·98
$l-L$ ... ... 118°·64	Call the sum A ... +1·47
From the tables $P = 359°·58$, $a = 30''·59$, $b = -10''·30$	$\log b$ ... ... +1·01
	$\cos (l-L)$ ... ... −9·68
	Call the sum B ... +0·69
	$\frac{A}{B} = \tan (p-P)$... +0·77
	$p - P$ ... ... 79°
	Add p... ... ... 359°
	p ... ... 79°
	$\sin (p-P)$ ... ... +9·99
	$\frac{A}{\sin (p-P)}$ ... ... 1·47
	s ... ... 29·3

THE FOURTH COMET OF 1874.—Dr. Holetschek, of the Observatory of Vienna, has investigated definitive elements this comet, which was discovered on August 19, 1874, by Coggia at Marseilles. He uses four normal places: for Aug 21, September 18, October 10, and November 9. For the normals we presume he will have made use of a fine series observations made with Col. Tomline's 10-inch refractor at Orwell Park Observatory, near Ipswich, by Mr. J. L. Plummer which extends, we believe, considerably beyond observa published so far from other observatories. With Col. Tom line's refractor the comet was followed until the middle November, and great care appears to have been taken with the observations and reductions. They form one of the very best series that has obtained for some years at an English observa tory. Dr. Holetschek infers that the comet was moving in elliptic orbit with a period of about 300 years. His orbit is follows:—

Perihelion Passage, 1874, July 17·68463, Greenwich M.T.

Longitude of perihelion	5° 26′ 13″ } M. Eq. 1874·0
,, ascending node ...	215 50 47 }
Inclination	34 7 54
Excentricity	0·9622257
Log. perihelion distance	0·227275
Semi-axis major	44·671
Period of revolution	298·6 years.

The comet with these elements might approach pretty near to the planet Uranus near the ascending node, but we might rather look to an encounter with Mars at the opposite node as the cause of ellipticity of orbit, the radii-vectores being there identical, with but small difference of latitude.

ANCIENT STAR-POSITIONS.—In the *Vierteljahrschrift der Astronomische Gesellschaft*, 16 Jahrgang, Dr. O. Dunckwort has tabulated the positions of forty-six fundamental stars of the *Berliner Jahrbuch* for the commencement of each century from − 2000 to + 1800. He adopts Leverrier's precession constants for 1850, and takes account of the proper motions. The tables are preceded by a discussion of formulæ and comparison of constants which will be of service to any one who may have

Digitized by Google

occasion to carry back to a distant epoch the place of a star not included in Dr. Danckwortt's list. The values of the arcs A, A', and θ, are given for the beginning of every century within the above period. The place of the present Pole-star for the year −2000 is found to be R.A. 335° 10′ 0″, Decl. +67° 34′ 30″.

WE may mention that the formulæ for the reduction of the places of stars to distant epochs are investigated in a very interesting paper by Prof. Schjellerup, which Dr. Copeland and Mr. Dreyer have translated in No. 2 of *Copernicus*, and which the reader who desires to acquaint himself with the application of the rigorous method of taking account of precession should consult.

PHYSICAL NOTES

THE conducting power of metals for heat and electricity has lately occupied several physicists. Prof. Lorenz of Copenhagen, employing two methods (*Wied. Ann.*, Nos. 7 and 8), gets these results: (1) for the better conducting metals, a confirmation of Wiedemann and Franz's law, that the ratio of the two conductivities, both at 0° and at 100° is nearly constant; in the inferior conductors it increases much with decreasing conductivity; (2) in all metals except iron, the ratio $\frac{k_{100}}{\kappa_{100}} : \frac{k_0}{\kappa_0}$ is constant, and approximately equal to 1·367 (k and κ denoting the conductivities for heat and electricity respectively). Thus, for absolute temperature T, $\frac{k}{\kappa} = T \times$ constant.

A "MEDICAL hydrotelephone," contrived by Prof. Sabatucci (*Riv. Sci. Ind.*) is of the following nature:—Two lead cylinders 5 ctm. in diameter and ½ ctm. thick) are closed each with two very fine iron laminæ. To the anterior part of each is fitted a wooden mouthpiece (like that of a Bell telephone) connected to a caoutchouc tube, through which one may hear at a distance. The posterior part has a very sensitive electromagnet communicating with a microphone and battery. One tube is applied to either ear. Words or sounds produced before the microphone, and heard but faintly, are rendered intense and distinct by introducing liquid into the cylinders (the less dense the liquid the better). Two sounds may be compared, and their intensity exactly measured, by varying the quantity of the liquid and noting the effects through the tubes. Various applications of the apparatus, in clinical medicine especially, are looked for.

THE effects of lightning on trees placed near a telegraph wire are forcibly illustrated by phenomena lately observed by M. Montigny (*Bull. Belg. Acad.*, No. 7) on a portion of the road from Rochefort to Dinant; which runs from east to west, first on level ground and between poplars for about 1500 metres, then rises gradually 61 metres through woods to a wooded plateau some 200 metres in extent, then comes down to another plain. Of the poplars bordering the road on either side those on the north side, next the telegraph line, have largely suffered, 80 out of 500 having been struck, or about a sixth; those on the other side are very rarely struck. The plain presents only one case, and that doubtful. The instances multiply with increased elevation, and in the wooded plateau on the top reach a maximum (64 per cent.). The most violent discharges have been on the west side of the plateau and rising ground, which is generally first reached by the storms, and the injuries to trees are mostly opposite and under the level of the wire. M. Montigny supposes that while the wire is strongly electrified by induction, the lightning does not strike it, on account of its relative insulation, but strikes the neighbouring poplars directly, which, wet with rain, afford an easier passage for the electric fluid to the ground.

M. PICTET has examined seven varieties of steel (chiefly from a Sheffield and a Vienna house) with regard to magnetic power (*Arch. des Sciences*, August 15). This power he finds to depend on the presence of carbon in the iron, and the aggregation of these substances. One of the two steels giving the best results had ⅞th per cent. of carbon. Samples with 1½ and 1⅛th per cent. were inferior. German steel of poor quality (for springs) yet made a good magnet; it had little homogeneity, and consisted of an intimate mixture of iron, and iron cemented with a small proportion of carbon. A too-small proportion of carbon suppresses or weakens the remanent magnetism. M. Pictet also finds that the increase of magnetic power in a magnet through the mere presence of the armature in contact is a certain fact for some qualities of steel, but not for all. The first magnetic passes develop nearly the whole of the remanent magnetism in all artificial magnets. Detachment of the armature by the dynamometer seemed to have no action on the magnetic power, only the slipping of the armature when near rupture must be avoided.

AN experimental inquiry into the production of tones by passage of gases through slits is described by Herr Kohlrausch in *Wiedemann's Annalen* (No. 8). The principal results are these: (1) For all widths of slit between 0·2 mm. and 1 mm. and all densities of gas employed, the pitch n may be represented as linear function of the velocity of outflow u by the formula $n = k(u - u_0)$, where u_0 and k are constant for a given width of slit and variety of gas; (2) with increasing width of slit (0·2 mm. to 1 mm.) u_0 decreases, k increases; (3) u_0 and k (for air) are as good as independent of the thickness of the slit (*i.e.* the thickness of the brass plates forming it), from 1 mm. to 9 mm.; (4) with increasing density of gas (0·7 to 1·5) u_0 generally decreases, k increases, *i.e.* the tones, *ceteris paribus*, become higher; (5) u_0 and k depend in no small measure on other properties of gases beides density; (6) starting from wide slits with constant velocity of outflow, the pitch increases pretty uniformly with narrowing of the slit, reaches a maximum with widths between 0 35 mm. and 0·27 mm.—with thicker slits, smaller pressures, and less dense gases, sooner than in the opposite cases—and then decreases more and more quickly with the width of slit; (7) this maximum pitch characteristic for each velocity of outflow occurs with a greater width of slit, the less the velocity. From a comparison with Strouhal's experiments on the tones excited by motion of cylindrical bodies in air, the author concludes that the production of slit-tones is to be referred to like causes to those of wire-tones.

AN electrophotometer recently described by Dr. Nachs (*La Natura*, August 1) has the following arrangement:—A wooden case opening on one side and above is divided into two compartments, an upper and a lower. The lower contains in the inner part a dry pile of 200 elements, and in the outer a Jacobi rheostat, the cylinder of which has thirty windings (the number introduced into circuit by turning a handle is precisely indicated). The upper compartment has interiorly a galvanometer, and exteriorly an adjustable truncated cone with inner surface blackened, and within it a small selenium cell similar to those used by Bell and Tainter, to receive the light. This cell and the three other electrical instruments are connected by wire. The mode of action will be readily comprehended.

MR. MILNE has observed (*Zeits. f. Kryst.*) that if a suspended quartz ball be allowed to impinge in various ways upon a fixed ball of lime spar, or if the ball of lime spar be placed on a billiard table and the distance observed to which it is driven by the shock, in the former case the quartz ball rebounds furthest, and in the latter the lime spar ball is driven furthest, when the impulse is in the direction of the (crystalline) axes.

IN a paper to the Bremen Society of Natural Science, Herr Müller Erzbach describes experiments in which he sought to ascertain the relative tension of aqueous vapour over saturated solutions of different hygroscopic substances, the inclosed air being submitted for long periods to the action of these. 1. For saturated solutions one finds in the same series, soda, potash, chloride of calcium, an increase in the vapour-tensions, and a decrease in the contractions. 2. Phosphoric acid anhydride, concentrated sulphuric acid, and hydrate of potash deprived of water, present no essential difference in attraction of water. 3. Caustic soda and chloride of calcium, with small proportion of water, differ little in attraction of water, but they do not bind it so firmly as phosphoric acid or hydrate of potash. 4. Hydrate of soda can be completely deprived of water by inclosure with hydrate of potash. 5. The difference in tension of aqueous vapour over the anhydride of phosphoric acid and chloride of calcium nearly without water amounts to only a small fraction of a millimetre of mercury.

THE hypothesis that the luminiferous ether is at rest and the earth moves through it, has been lately put to experimental test by Mr. Michaelson of the U.S. Navy (*Amer. Journ. of Science*, August). Two pencils of light which have travelled over paths at right angles (one path being in the direction of the earth's motion) are permitted to interfere. On rotation of the apparatus 90° a measurable displacement, estimated at about one-tenth of the distance between the fringes, might be looked for (the author considered) if the hypothesis of a stationary ether were correct. The apparatus was first tried in the Physical Institute

Digitized by Google

in Berlin, then, for greater quiet, in the Astrophysicalisches Observatorium at Potsdam (it was very sensitive to vibrations). The interpretation of the results is that there is no displacement of the interference bands, and the hypothesis (which is presupposed in the commonly accepted explanation of aberration) is inferred to be erroneous.

THE expansion of solid sulphur has been studied by S. Scichilone of Palermo, in the case of natural crystals, and of such as had been heated after fusion to 140° and 240°. The tables (*Wied. Beibl.*, No. 7) show that the expansion depends essentially on the previous heating, inasmuch as different modifications of sulphur are thereby formed. In the first case we have the octahedral sulphur, in another the monoclinic, and in the third a mixture of the latter with that which is not dissolved in sulphide of carbon. In the first two cases the curve representing the volumes as a function of the temperature turns its convex side, in the third its concave side, to the axis of temperature.

GEOLOGICAL NOTES

THE recent geological exploration of the shores of Lake Baikal by M. Tchersky has been fruitful of important results for science. The rocks of which the mountains on the western shore are built up belong to three different ages: pre-Silurian (probably Laurentian), Silurian, and Jurassic. The Laurentian rocks afford several foldings running north-east, which enclosed basins of Silurian and Jurassic seas; as to recent formations they are only freshwater ones, and belong to the Tertiary and Post-pliocene; these last, which are remains of several smaller lakes, are found at a great height above the level of Lake Baikal. M. Tchersky's geological researches confirm the suggestion which was made several years ago on geographical grounds by M. Kropotkin, namely, that, like several other lakes, Lake Baikal consists of two longitudinal valleys, connected together in the middle part of the actual basin.

THE important coal-basin of the Don province of Russia has not hitherto been explored with accuracy. During last summer M. Domger undertook a thorough exploration of this interesting geological region, and, as we learn from a communication he has made at the December meeting of the St. Petersburg Mineralogical Society, his researches have led to important discoveries. Thus he discovered a great variety of crystalline rocks, porphyries, &c., and volcanic ores, within the coal-measures, which discovery thus extends the crystalline island of Southern Russia far eastwards as a strip about 500 miles long, which runs from north-west to south-east. At the same meeting the Society awarded its gold medal to M. Romanoffsky for his researches in Turkestan.

M. DOKOUCHAIEFF'S researches on the soils of Russia seem to establish a very interesting fact as to the distribution of black-earth. The typical black-earth occupies an elongated zone directed from south-west to north-east from Kishineff, through Kharkoff, Voronesh, Simbirsk, to Bougoulina in the province of Oufa; in this zone the black-earth contains from 7 to 12 per cent. of humus, and from both sides to north-west and south-east it is accompanied by two other elongated zones, where the black-earth contains only 5 to 7 per cent. of humus, whilst the other parts of Russia afford only sporadic spots of black-earth.

M. MOUSHKETOFF'S paper on the glacier of Zerafshan, which appeared in a recent number of the *Izvestia* of the Russian Geographical Society, contains further details about the expedition which has explored the glacier throughout its whole length, from its lower extremity to the sixteen miles distant and 13,800 feet high pass of Matcha, whence another glacier, that of the Zardala river, descends on the north-eastern slope for 2200 feet, by a series of mighty icefalls. The paper is accompanied with a pretty map which shows this grand ice-world, where no less than thirteen secondary glaciers are feeding the ice-stream of the Zerafshan. We notice in this paper that formerly the Zerafshan glacier descended far lower than now. M. Moushketoff says that thirty-three miles below its actual extremity, namely, at the village Diaminor, there is a beautiful terminal-moraine which crosses the valley and unites with three longitudinal moraines. Immense boulders, thirty-five and forty feet in diameter, and consisting of granite, syenite, and gabbro, cover the whole space between these old moraines and the actual ones, so that there cannot be the least doubt as to the glacier having descended for at least thirty-three miles lower than now. But when we consider how the composition of the drift changes lower down in the valley, the loess, which is the wealth of the inhabitants in the lower countries, changing into mighty conglomerates with immense boulders, we are much inclined to think, that the former glaciers descended yet far lower. Therefore we observe with some regret that M. Moushketoff gives too little attention to the diluvial formations of the Upper Zerafshan and to their relations to the loess.

GEOGRAPHICAL NOTES

WHEN Humboldt determined for the first time the average heights of continents, he could not, because of the want of data, determine that of Africa. Now Dr. Chavanne publishes, in the *Proceedings* of the Geographical Society of Vienna (vol. xxiv.), an elaborate paper on this subject, accompanied with a hypsometrical map of the African continent, which is based on more than 8000 hypsometrical measurements. After a thorough discussion of the relative value of various measurements, Dr. Chavanne discusses the average heights of separate parts of Africa, and by how much each of them would raise the continent if its mass were distributed over the whole of the surface of Africa. He finds that the Atlas Mountains, if distributed over the surface of Africa, would produce an elevation of 26 metres; the Sahara, 122 metres; the plateaux of Soudan, 85 metres; those of Central and South Africa, 129 metres; and so on: and he accepts for the average height of the whole of the continent no less than 661·8 metres (with a probable error of ± 21 metres), which figure he considers to be rather below the truth. This very high figure obviously is the result of the very great extension of high plateaux, which we do not find to such an extent even in Asia.

IN the Annual Report of the Surveyor-General of India, which, though it has been printed for months, has only just been allowed to appear, prominence is given, under the heading of Trans-Frontier Exploration, to an attempt to determine the position of the head-waters of the Irrawaddy by Capt. J. E. Sanderson, through the agency of a native surveyor whom he had trained in imitation of the late Col. T. G. Montgomerie's renowned staff in India. This surveyor alleges that he ascended the river to Mogung-poon, near the point where it divides into two great branches, the Malee and Mehka. The surveyor, we believe, gives as an explanation of his not having prosecuted his journey to a more successful termination, that he was attacked and robbed by wild tribes; but we hear privately that persons in Burma, well qualified to form an opinion, attach little credence to any of the surveyor's statements, and we fear, therefore, that the position of the head-waters of the Irrawaddy is still an unsolved problem.

THE Geographical Society of the Pacific is the title of a new Society formed at San Francisco. The Secretary is C. Mickle Grant, F.R.G.S. The objects of the Society, it is stated, are to encourage geographical exploration and discovery; to investigate and disseminate geographical information by discussions, lectures, and publications; to establish in the chief city of the Pacific States, for the benefit of commerce, navigation, and the industrial and material interests of the Pacific Slope, a place where the means will be afforded of obtaining accurate information, not only of the countries bordering on the Pacific Ocean, but of every part of the habitable globe; to accumulate a library of the best books on geography, history, and statistics; to make a collection of the most recent maps and charts, especially those which relate to the Pacific coasts, the islands of the Pacific, and the Pacific Ocean; and to enter into correspondence with scientific and learned societies whose objects include or sympathise with geography. The Society will publish a *Bulletin* and an annual *Journal*.

WE learn from the Annual Report for 1880-1881 of the Swiss correspondent of the Geographical Society of Vienna that the following geodetical and geological work was done in Switzerland:—The Geodetical Commission has published the seventh fascicule of the "Nivellement de Précision de la Suisse," which contains the measurements done during the years 1877 to 1879 on the lines of Monte Cenero to Chiasso, Reichenau to Sargans and Andermatt, and Süss to Landquart and Chur-Vienna, uniting thus the Swiss measurements with the Italian ones. The Geological Commission publishes the fourth volume of its new series, containing the important work, by Dr. Baltzer

Digitized by Google

on the zone of contact between the gneiss and the limestones of the Berne Oberland; another most interesting work, on the distribution of heat in the interior of the St. Gothard Tunnel, is pursued by Dr. Stapff, and a preliminary notice about it, with maps, has just appeared in the Quarterly Reports of the Federal Council. (vol. vii.). It shows that the temperature of rocks increases to a great degree to the interior of the tunnel, being only 17° Celsius and 19°·7 at the southern and northern extremities of the tunnel, and as high as 30°·8 in the middle parts of it, the decrease at the outer ends being attributed by Dr. Stapff to the cooling influence of the water which circulates in the rocks. As to the geological information collected by Dr. Stapff during his work in the tunnel, which appears complete (with sixty sheets of maps and profiles) in the Reports of the Federal Council, a short *résumé* of the whole has already appeared in a separate fascicule of these Reports, with a geological outline of the tunnel. We notice also in this branch a valuable paper, by M. Salis, on the erosion of the Nolla River, tributary of the Rhine, which has appeared in the engineering paper, *Die Eisenbahn*, published at Zurich.

THE various races which inhabit Austria are studied by Dr. Goehlert in the last number of the *Proceedings* of the Geographical Society at Vienna (vol. xxiv.), with respect to the length of the body. After having collected more than one and a half million of such measurements, which were done on recruits during the years 1870 to 1873, Dr. Goehlert has dressed a map in which he has shown the average height of young men, twenty to twenty-three years old, in Austria. The Dalmatians are the tallest; next to them come the Serbo-Croats and Slovenes, and then the Germans and the Czechs; further down come the Ruthenes and Roumanians, and the smaller ones are the Magyars and Poles, especially the Mazours. But there are also two or three distinct average heights among the Germans, the Slaves, and the Magyars, those of middle Hungary, between the Danube and the Theiss rivers, being far taller than those of the flat country on the left bank of the Theiss. It is most probable, as M. Broca has shown with regard to France, that these notable differences of height among the same race show that there were two, or more, different branches which constituted what we consider now as a single race. As to the supposed decrease of height observed in France, Dr. Goehlert supposes that in Bohemia, which has furnished during this century no less than 600,000 men to the Austrian armies, the decrease of average height can be estimated at little under 39 millimetres during the last hundred years, this decrease being due to the continuous taking away of tall men from the country. He shows also that, the standard height being the same for all provinces of Austria, the provinces where men are taller suffer proportionately more from recruiting.

THE seventeenth meeting of the Swiss Alpine Club was opened at Basel on September 10. The Annual Report shows that since its foundation the Club has built thirty-one huts, or *refuges* for climbers. The Club has also endeavoured to give a certain instruction to guides, and during this year an insurance society has been instituted for them. As to its publications, it has published sixteen volumes of year-books, which contain plenty of valuable information on the Swiss Alps, and publishes two papers, the *Écho des Alpes* and the *Neue Alpenpost*, which have contributed much to the development of Alpine literature. At its last meeting Mr. Ed. Whymper and the meteorologist, Prof. Hamen, were elected Honorary Members.

THAT part of the Ala-taou Mountains which is situated north-east from Tashkent, at the sources of the Arys, Talas, and Pskem Rivers, and which remained until now quite unknown, is described in the *Izvestia* of the Russian Geographical Society (vol. xvii. fascicule 3) by Col. Ivanoff. It is a very complex system of mountains, from 10,000 to 16,000 feet high, covered with mighty glaciers. The upper clefts have still conserved a good deal of forests, and the high Alpine pasturages are the grazing ground for the numerous herds of Kirghizes, as well as for the great species of *Ovis*, common to Thian-Shan. Col. Ivanoff has found numerous proofs that formerly the glaciers had a greater extension than now, and that they formed in the valley of the Maydan-tal River a mighty glacier which descended as low as 7000 feet, but he did not discover traces of a general glaciation.

HERR ERNST MARNO gives, in the last fascicule of the *Memoirs* of the Geographical Society of Vienna (vol. xxiv. Nos. 6, 7, 8, and 9), an interesting description of his expedition for the destruction of the *setts* of the Nile, that is, of the great grass-islands which are formed during the inundations of the steppes watered by the Bahr-el-Gebel and the Bahr-el-Abiad. The accumulation of grass which is driven away during the inundations constitutes, as is known, wide grass-islands, or *setts*, which bar up the river, and, when not cut through for several years, gradually increase by fresh grass and slime, and soon constitute true floating islands twelve and fifteen feet thick, which soon reach even the bottom of the river. It is with the greatest difficulty that Marno's steamer cut passages through these islands and destroyed the smaller ones.

WE see with pleasure that the Austrian Tourists' Club, which numbers as many as 300 members, has begun to publish fortnightly a *Tourists' Newspaper*, richly illustrated, which has as contributors many well-known scientific writers.

IN the *Monatsschrift für den Orient* for September, Herr von Schweiger-Lerchenfeld has a long article full of valuable information on Tripolitania, *à propos* of recent doings in North Africa. There is also an interesting letter from Ernst Marno on the Sudan.

IN the *Bulletin* of the Antwerp Geographical Society (tome vi. 3e fasc.) M. L. Delavaud has brought together a number of valuable notes on the climate of Africa, interesting both from a scientific and a practical point of view.

THE last number of the *Izvestia* of the Russian Geographical Society contains papers, by M. Maeff, on the roads leading from Karshi to the Amu-daria River, and on the valleys of Vaksh and Kafirnahan; by M. Ivanoff on the upper parts of the Talas Alataou, and a map showing M. Mikluho-Maclay's travels in the Melanesian Islands.

THE eighth volume of the *Memoirs* of the Russian Geographical Society, for the section of ethnography, contains several valuable papers on the middle parts of the valley of Zerafshan, on the basin of Lob-nor, on the valley of Ferghana, on the Bekdons Shahrisabs, on the journey of Jenkinson to Khiva in 1559, on the Khiku-nor, and on the customs of the Tartars of Kazan.

IN a pamphlet entitled "Geography" Messrs. Ramsey, Millett, and Hudson have reprinted, from the Kansas City *Review of Science and Industry*, an interesting collection of official documents relating to United States Arctic colonisation and exploration in 1881. There are now no less than six expeditions in progress under Government control, which are divisible into two classes, one comprising those sent out for purposes of exploration and scientific research and the other those whose object is of a humanitarian nature. To the former class belong the *Jeannette*, Lady Franklin Bay, and Point Barrow expeditions, while the latter includes the *Rodfars*, *Alliance*, and *Corwin*, all chiefly engaged in searching for the *Jeannette* and missing whale-ships.

The just published *Bulletin* of the Belgian Geographical Society includes a paper by Capt. Verstraete on the great lakes of intertropical Africa from the fifteenth to the nineteenth century. There are also maps of Borneo, the new northern frontier of Greece, &c., which exhibit considerable roughness of execution.

ECONOMICS AND STATISTICS, VIEWED FROM THE STANDPOINT OF THE PRELIMINARY SCIENCES[1]

THE object of the present paper is to show the relation of the preliminary sciences to statistics and economics, and to attempt to make the transition from the former studies to the latter simple and attractive to the scientific man. This must evidently be done by constructing a classification of social knowledge avoiding all immediate reference to practice. That such a classification does not at present exist cannot be better evidenced than by Mr. Baden-Powell, who has kindly drawn my attention to the conclusion of his paper, read on the previous day, "On Protection in Young Communities," in which he states the difficulties he has encountered in many departments of his researches because of the different methods of classification adopted in otherwise excellent statistical records, and insists that "uniformity in the method of registering statistical facts is of the utmost importance to comparative investigations," so that

[1] Abstract of a paper read before Section F of the British Association, 1881, by P. Geddes, F.R.S.E.

Digitized by Google

"it would be of great importance if such uniformity could be secured in the future."

A survey of the statistical records of various countries, whether under the same or different political rule, shows the most extreme discord, while a detailed examination of the schemes which have been as yet proposed by statisticians results in their rejection as unscientific—the very latest of such schemes being curiously analogous to the very earliest of classificatory attempts in biology. A criticism of the innumerable definitions of statistics, some of which claim statistics as a science, others as a method, others as both or neither, leads to the acceptance of the view recently sustained by Hooper (J.S.S. 1881), that statistics is simply a quantitative record of the observed facts or relations in any branch of science,—a definition which may conveniently be extended diagrammatically as follows:—

RECORD OF FACTS AT GIVEN TIME.

Qualitative	Quantitative			
	Numerical	Linear	Plane	Solid
		Graphic		
Statements.	Statistics.			

By combining such successive records we obtain history, and statistics and history are thus seen to be, within certain limits, the common property of the sciences—all save logic, where there are no ideas of quantity, being statistical, and all save logic, mathematics, physics, and chemistry, where conditions and properties are constant, being historical; the current notions of statistics and history as distinct sciences, or as distinct scientific methods, being therefore entirely erroneous.

The application of the above diagrammatic definition of statistics to all the sciences clearly illustrates the continual progress from qualitative to quantitative knowledge which goes on in each, and the increase of definiteness which quantitative knowledge constantly tends to assume. Thus while the common name of a chemical compound, say sulphate of iron, expresses only a qualitative relation, its ordinary chemical formula, $FeSO_4$, reaches the numerical state, and its graphic and glyptic formulæ are respectively the plane and solid representations of the same relation of quantity. So, too, the astronomer has his star maps and orrery, the biologist his figures and diagrams, while the sociologist so often requires similar aid that the French Government has recently established a Bureau de Statistique Graphique. So by piling up successive graphical representations of statistical observations, a solid historical model might often be constructed. A geologist, for instance, by piling map upon map of a given island at successive times (the margin being, of course, cut away) would thus construct a solid model which would graphically exhibit the changes of increase and decrease, local and general, throughout the entire period.

But what are the desiderata of a system of classification? It must be natural, not artificial,—capable of complete generalisation and specialisation, universal in application, simple of understanding, and convenient in use. Immeasurably the highest example of such a classification is presented by botany and zoology, and it is therefore the biologist, not the logician or the mathematician, and still less the metaphysician or the political economist, whose training prepares him to undertake the still vaster task of classifying the infinitely numerous and varied phenomena of society.

Taking an actual compendium of miscellaneous statistics, we have first then to separate out in order the actual statistics of the preliminary sciences, mathematical, physical, chemical, astronomical, geological, &c., and leave these to their special cultivators. Social statistics now alone remain, and to classify these naturally we must ascertain the fundamental scientific truths respecting society. Just as the biologist is accustomed to classify man along with inferior organisms, and to trace the fundamental resemblances in structure and function which his organisation presents to theirs, so he must inquire wherein human society resembles the societies formed by the lower animals, the more so as no one disputes that these fall strictly within his province (see Huxley, "Anat. Invert." p. 1). As the term indeed assumes, some general truths must be common to societies of *Apis*, *Castor*, and *Homo* alike, and this must underlie our classification of social facts.

First, then, a society obviously exists within certain limits of space and time. It consists of living organisms which modify surrounding nature, primarily by using up matter and energy. Again, they apply this matter and energy to the maintenance of their life; *i.e.* the support of their biological functions. Finally, these organisms are modified by environment.

These *sociological actions*, as we may henceforth call them, at once enable us to classify out the facts relating to every society as follows: (A) those relating to the land and space occupied by the society; (B) those relating to matter and energy utilised by the society; (C) those relating to the organisms composing the society; (D) those relating to application of the utilised matter and energy to the society; (E) those relating to the results of the previous conditions upon the organisms. These considerations are developed in a series of tables exhibited on diagram on the wall; and an extremely condensed summary is given on the following page.

These tables, which may be read either separately, horizontal, or in vertical series (the left-hand vertical series viewed as entries on the credit side of a balance sheet), developed into detail, and shown to be applicable to societies alike, whether animal or human, civilised or savage, include the facts (A) of political geography; (B) of physics, geology, botany, and zoology, of technology and arts, transport and commerce, in short of the means of production; (C) of anthropology, together with the Registrar-General's reports and the census; (D) of distribution and consumption; (E) of a large body of observations made by physiologists, educationists, and philanthropists dealing with modifications of the organisms by their environment. These tables, therefore, while endeavouring to classify all the statistics, attempt nothing short of an organisation of the sciences into a more definite and coherent body of knowledge than they have formed heretofore.

It was then shown that while the above outlined results are in entire harmony with the economic theory of the geographer, the physicist, the biologist, the anthropologist, the demographer, they furnish grounds for a destructive criticism of existent systems of political economy, in so far as these lack intellectual completeness; the best proof of this being their inapplicability to utilise and reconcile the labours of writers of the contending schools, statistical and economical alike.

The application of the conceptions of physics to the interpretation of social facts was then alluded to, the question of money being taken as an example. This next depend neither upon compensation for risk or loss, nor abstinence, nor wages of superintendence, as economists (Fawcett, "Pol. Econ."), but yet to be explained from the wealth of other members of the community, as supposed by its opponents, but usually to arise, at all times at least, from the appropriation of the means of nature, and generally speaking, from the exploitation of the sun.

But the severest test which can be imagined is to apply the ideas of the present paper to the study and classification of the other papers read during the meeting of the section in preparation within such short limits of time has been possible. The first, "On Societies of Commercial Geography," relates to the study of territory (Tables A); the second, "Census," is, in the language of Table B, I., inquiry whether the cultivation of plants or animals be more profitable in the given area; the third, "Report of Committee on Teaching," relates to the state and treatment of cerebral functions of natives in the given society; the fourth, "On Agricultural Statistics, Prospects," is at once classified with the second; the "Law of General Banking Law," &c., relates to the evolution of commerce (Table B, II., Movement), and so on.

So, too, with the anthropological papers—all such as those on Caves and Kitchen-Middens," is a statement of the means of living production, partition, and consumption among the community, while the next, "On the Statues of the Incas of Hungary," supplies facts to be classified under Hungarian ethnisms, structure. Nor are the other sections behind in

papers essentially economic: witness the numerous interesting papers read to Sections A and G, on the applications of electric energy, and, best of all, the presidential addresses to those sections, of which both were devoted to economic physics, or rather, as the subject should be called, physical economics.

Finally, if the preceding axioms and the soundness of the above classification of social facts be not disproved, it follows that three out of the four great reforms demanded in Mr. Ingram's presidential address,[1] and repeated and enforced in Mr. Grant Duff's, are here introduced into the conduct of economic research, namely, "(1) that the study of the economic phenomena of society ought to be systematically combined with that of the other aspects of social existence; (2) that the excessive tendency to abstraction and to unreal simplifications should be checked; (3) that the *à priori* deductive method should be changed for the historical; while the fourth, that economic laws and the practical prescriptions founded on these should be conceived and expressed in a less absolute form," would readily also be exemplified if the limits of the present paper permitted reference to generalisation and to practice. Again, it is sufficient to quote Mr. Ingram's concluding proposals to show that these have been substantially adopted. The field of the section should be enlarged so as to comprehend the whole of sociology, "since the economic facts of society . . . cannot be scientifically considered apart, and there is no reason why the researches of Sir Henry Maine or Mr. Spencer should not be as much at home here as those of Mr. Fawcett or Prof. Price. Many of the subjects, too, at present included in the artificial assemblage of heterogeneous inquiries known by the name of anthropology really connect themselves with the laws of social development, and if our section bore the title of the sociological, the studies of Mr. Tylor and Sir John Lubbock would find in it their most appropriate place. I prefer the name sociology to that of social science."[2]

THE PROPER PROPORTIONS OF RESISTANCE IN THE WORKING COILS, THE ELECTRO-MAGNETS, AND THE EXTERNAL CIRCUITS OF DYNAMOS[3]

FOR the electro-magnet;

Let L be the length of the wire,

B ,, bulk of the whole space occupied by wire and insulation,

n ,, ratio of this whole space to the bulk of the copper alone (that is, let $\frac{1}{n}B$ the bulk of the copper),

A ,, the sectional area of wire and insulator,

R ,, the resistance of the wire.

For the working coil, let the corresponding quantities be L', B', n', R'. Lastly, let s be the specific resistance of the copper. We have—

$$B = A\,L$$

$$R = ns\frac{L}{A} = ns\frac{B}{A^2}.$$

Hence, $$A = \frac{\sqrt{(nsB)}}{\sqrt{R}} = \frac{K}{\sqrt{R}} \quad . \quad . \quad . \quad (1)$$

and similarly, $$A' = \frac{\sqrt{(n's'B')}}{\sqrt{R'}} = \frac{K'}{\sqrt{R'}} \quad . \quad . \quad . \quad (2)$$

where K and K' denote constants.

Now, let c be the current through the magnet coil, and c' that through the working coil, and let v be the velocity of any chosen point of the working coil. Denoting by p the average electromotive force between the two ends of the working coil, we have—

$$p = I\frac{c}{A}\frac{1}{A'}v. \quad . \quad . \quad . \quad (3)$$

where I is a quantity depending on the forms, magnitudes, and relative positions of B and B', and on the magnetic susceptibility of iron; diminishing as the susceptibility diminishes with increased strength of current, or with any change of R and R' which gives increase of magnetising force.

In the single-circuit dynamo (that is, the ordinary dynamo) c' is equal to c, but not so in the shunt-dynamo. In each, the whole electric activity (that is, the rate of doing work) is p or, by (3)—

$$I\frac{cc'}{AA'}v \quad . \quad . \quad . \quad . \quad . \quad 4$$

or, by (1) and (2)—

$$\frac{I\sqrt{(RR')}cc'v}{KK'} \quad . \quad . \quad . \quad . \quad 5$$

Of this whole work, the proportions which go to waste in heating the coils and to work in the external circuit are—

$$Rc^2 + R'c'^2 \quad . \quad . \text{ waste} \quad . \quad 6$$

$$\frac{I\sqrt{(RR')}cc'v}{KK'} - (Rc^2 + R'c'^2). \text{ useful work} \quad 7$$

By making v sufficiently great, the ratio of (6) to (7) (waste to useful work) may be made as small as we please. Our question is, how ought R and R' to be proportioned to make the ratio of waste to work a minimum, with any given speed? or, which comes to the same thing, to make the speed required for a given ratio of work to waste a minimum? To answer it, let r be the ratio of the whole work to the waste. We have, by (5) and (6),

$$r = \frac{I\sqrt{(RR')}cc'}{Rc^2 + R'c'^2}\frac{v}{KK'} \quad . \quad . \quad 8$$

For the single-circuit dynamo we have $c = c'$, and (8) becomes—

$$r = \frac{I\sqrt{(RR')}}{R + R'}\frac{v}{KK'} \quad . \quad . \quad . \quad 9$$

or $$r = \frac{I\sqrt{\{R(S-R)\}}v}{SKK'} \quad . \quad . \quad . \quad 10$$

where $$S = R + R' \quad . \quad . \quad . \quad . \quad . \quad 11$$

Suppose now S to be given, and suppose for a moment I to be constant. The problem of making r a maximum with v given, or v a minimum with r given, requires simply that $R(S-R)$ be a maximum; which it is when $R = \frac{1}{2}S$, that is, when the resistances in the working coil and the electro-magnet are equal. But in reality I is not constant; it diminishes with increase of the magnetising force. As it generally depends chiefly on the soft iron of the electro-magnet, and comparatively but little on the soft iron of the moving armature, or on iron magnetised by the current through the moving coils, it will generally be the case that I will, *cæteris paribus*, be diminished by increasing R and diminishing R'. Hence the maximum of r is shown by (10) to require R' to be somewhat greater than $\frac{1}{2}S$; how much greater we cannot find from the formula, without knowing the law of the variation of I.

Experience and natural selection seem to have led in most of the ordinary dynamos, as now made, to the resistance in the electro-magnet being somewhat less than the resistance in the working coil, which is in accordance with the preceding theory.

Whether the useful work of the dynamo be light-giving, power, or heating, or electro-metallurgy, we may, for simplicity, reckon it in any possible case by referring to the convenient standard case of a current through a conductor of given resistance E connecting the working terminals of the dynamo. This conductor, in accordance with general usage, I call the "external circuit," which is an abbreviation for the part of the whole circuit which is external to the dynamo. In the case of the single-circuit dynamo the current in the external circle is equal to that through the working coil and electro-magnet, or c of our notation. Hence, by Ohm's law—

$$c = \frac{p}{E + R + R'} \quad . \quad . \quad . \quad . \quad 12$$

or, by (3), (1), and (2),

$$c = c\frac{I\sqrt{(RR')}v}{KK'(E + R + R')} \quad . \quad . \quad 13$$

Hence either $$c = 0 \quad . \quad . \quad . \quad . \quad . \quad 14$$

or $$I = \frac{KK'(E + R + R')}{\sqrt{(RR')}v} \quad . \quad . \quad 15$$

The case of $c = 0$ is that in which

$$v < \frac{KK'(E + R + R')}{I_0\sqrt{(RR')}} \quad . \quad . \quad 16$$

where I_0 denotes the value of I for $c = 0$. To understand it remember we are supposing no residual magnetism. For any speed subject to (16), the dynamo produces no current. When this limit is exceeded the electric equilibrium in the circuit becomes unstable; an infinitesimal current started in either direction rises rapidly in strength, till it is limited by equation (15), through the diminution of I, which it produces. The

[1] "On the Present Position and Prospects of Political Economy" (British Association, Dublin, 1878).

[2] Quoted by Mr. Grant Duff, Presidential Address to Section F, 1881.

[3] Paper read at the British Association, York, 1881, by Sir William Thomson, F.R.S.

Digitized by Google

egarding I as a function of c, we have in (15) the equation mathematically expressing the strength of the current maintained by the dynamo when its regular action is reached. Using (15) in (10) we find—

$$r = \frac{E + S}{S} \quad . \quad . \quad . \quad . \quad . \quad (17)$$

which we all knew forty years ago from Joule.

In the shunt-dynamo the whole current, c', of the working coil branches into two streams, c through the electro-magnet, and $c' - c$ through the external circuit, whose strengths are inversely as the resistances of their channels. Still calling the resistance of the external circuit E, we therefore have—

$$c R = (c' - c) E, \text{ which gives } c = \frac{E}{R + E} c' \quad . \quad (18)$$

Hence, by Joule's original law, the expenditures of work per unit of time in the three channels are respectively

$$\left.\begin{aligned} &R' c'^2 \quad . \quad . \quad . \quad \text{working coil} \\ &R\left(\frac{E}{R+E}\right)^2 c'^2 \quad . \quad . \quad \text{electro-magnet} \\ &E\left(\frac{R}{R+E}\right)^2 c'^2 \quad . \quad . \quad \text{external circuit} \end{aligned}\right\} \quad . \quad (19)$$

Hence, denoting as above by r the ratio of the whole work to the work developed in the external circuit, we have—

$$r = \frac{R' + R\left(\frac{E}{R+E}\right)^2 + E\left(\frac{R}{R+E}\right)^2}{E\left(\frac{R}{R+E}\right)^2} \quad . \quad (20)$$

$$\left.\begin{aligned} \text{whence} \quad R^2 r &= R'\frac{(R+E)^2}{E} + R(R+E) \\ &= \frac{R' R^2}{E} + (R + R')E + R(2R' + R) \end{aligned}\right\} \quad (21)$$

Suppose now R and R' given, and E to be found; to make r a minimum. The solution is—

$$E = \sqrt{\frac{R' R^2}{R + R'}} \quad . \quad . \quad . \quad . \quad . \quad (22)$$

and this makes

$$r = 2\sqrt{\frac{R'(R + R')}{R^2}} + \frac{2R' + R}{R} \quad . \quad . \quad (23)$$

Put now

$$\frac{R'}{R} = e \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (24)$$

(22) and (23) become

$$E = \sqrt{\frac{R R'}{1 + e}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (35)$$

and

$$r = 1 + 2\sqrt{\{e(1 + e)\}} + 2e \quad . \quad . \quad . \quad (26)$$

For good economy r must be but little greater than unity; hence e must be very small, and therefore *approximately*

$$\left.\begin{aligned} E &= \sqrt{(R R')} \\ \text{and} \quad r &= 1 + 2\sqrt{e} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (25)$$

For example, suppose the resistance of the electro-magnet to be 400 times the resistance of the working coil—that is $e = 400$—and we have, approximately,

$$E = 20R', \text{ and } r = 1 + \tfrac{1}{20}.$$

That is to say, the resistance in the external circuit is twenty times the resistance of the working coil, and the useful work in the external circuit is approximately $\frac{19}{21}$ of that lost in heating the wire in the dynamo.

FUNCTIONAL METAMORPHOSIS OF MUSCLES[1]

THERE is no system in the animal body to which the axiom of Guérin, viz., that "function makes the organ," applies with greater force than to the muscular system. Every student of comparative myology knows that according to the use required of a muscle we have alterations in its volume and connections, or indeed its total disappearance, should its further services in the animal economy be dispensed with. These are the factors which render muscular homologies in many cases so difficult to determine. There is one change, however, which is much more common than is generally believed, viz., the transformation of a muscle into fibrous tissue, or, in other words, its replacement by a ligamentous structure possessing attachments similar to those of its muscular ancestor. It might almost be laid down as a law that whenever a muscle ceases to be of use for contractile purposes, and when, from its attachments, it might be of service as a ligament, that it gradually in course of time becomes transformed into fibrous tissue, and is handed down to posterity in this condition. Indeed should it merely be a case of comparative value, and should the balance of utility be in favour of a ligament, then also will this metamorphosis in all probability take place. Of all adaptations in the muscular system this is perhaps the most beautiful, and instances of it are by no means rare. Thus, in the feet of the armadillo, orycteropus, pig, walrus, and several other animals, certain of the intrinsic pedal muscles have become fibrous bands, indubitably retained for some definite purpose, although their obvious function is often obscure. The most striking examples of this, however, are to be found in the feet of the horse, ox, sheep, camel, and their allies. In these we are able not only to demonstrate with the utmost precision the particular muscles that have become ligamentous, but also the process by which the change has been brought about, and the *rationale* of the transformation.

The *suspensory ligament of the fetlock* in the horse is an exceedingly powerful structure, which lies in the sole of the foot (*i.e.* upon the posterior aspect of the metatarsal bone) under cover of the flexor tendons. It plays an important part in the mechanism of the limb. Its attachments are such that it prevents over extension at the fetlock or metatarso-phalangeal joint, and its value in this respect is evidenced by the fact that when it is ruptured the horse becomes what is termed by veterinary surgeons "broken down." In this condition the fetlock joint sinks downwards towards the ground, whilst the hoof is tilted forwards and upwards.

This ligament is admitted on all hands to be derived from the intrinsic pedal muscles by a transformation of the muscular elements into fibrous tissue; indeed it bears its history written upon its face. Almost invariably a narrow streak of striated muscular fibres can be detected upon its superficial surface which points to its muscular origin. Upon its deep surface fleshy fibres in greater abundance are observed, but these are very pale, owing to a large admixture of fatty tissue.

The question now comes to be—Which of the intrinsic pedal muscles have entered into the formation of this ligament? In making this inquiry we have to keep two points in view: (1) that in the horse the middle or third digit is alone fully developed; and (2) that in a typical pentadactylous foot this digit is supplied by three intrinsic muscles, viz.: a two-headed flexor brevis, and two abductors or dorsal interossei (the second and third) inserted one upon either side of the digit. It is reasonable to conclude, therefore, that the suspensory ligament of the fetlock is derived from one or more of these muscles. But independent remnants of the two dorsal interossei are present, in addition to the ligament, which clearly proves the *flexor brevis medii* to be the source of this structure.

The dorsal interossei in the foot of the horse are of peculiar interest. They are so minute that they can exercise little or no influence upon the movements of the pes. They are simply to be regarded as vestiges of former greatness, and as pointing to retrograde development. They undoubtedly constitute a link in the soft parts between our modern monodactylous horse and its three-toed ancestor. They lead us back to a time when in the foot of this animal there were two distinct interosseous spaces, each filled by a well-marked interosseous muscle.

Still stronger evidence that the suspensory ligament originates solely from the *flexor brevis* of the middle digit is obtained by making thin transverse sections through its substance. We then observe that the sparse remains of muscular tissue are not confined to the surface of the structure, but penetrate into its midst. When the specimen is held against a dark ground, two crescentic opaque outlines are noticed lying side by side in its substance. These undoubtedly represent tracings of the two heads of the flexor brevis, out of which the ligament is developed. On subjecting the outlines to microscopic examination, we find that they are mainly composed of muscular fibres, but every here and there the continuity of this tissue is broken by fatty tissue, in which are observed transversely-divided nerves and blood-vessels.

In the ox, sheep, and camel the suspensory ligament performs the same office as in the horse. The presence, however, of two digits (the middle and annular) complicates somewhat its inferior attachments, in order that it may operate so as to prevent over-extension at both metatarso-phalangeal joints. In each of these animals the structure is undoubtedly formed by the two heads of

[1] Abstract of paper read at the York meeting of the British Association, by D. J. Cunningham, M.D., F.R.S.E., Senior Demonstrator of Anatomy, University of Edinburgh.

Digitized by Google

two muscles, viz., the *flexor brevis annularis* and the *flexor brevis medii*. Transverse sections of the ligament render this very evident.

In the suspensory ligament of the ox a considerable amount of muscular tissue is found upon both surfaces, and the transverse sections show that this penetrates into its substance in the form of four circular outlines which lie side by side. The fleshy fibres are more abundant than in the case of the horse, but still a considerable amount of fatty tissue enters into the construction of the outlines, and in this are placed nerves and blood-vessels. These four outlines are the remains of the four fleshy bellies of the two flexores breves which amalgamate and transform so as to constitute the ligament.

In the sheep not a trace of muscular tissue is to be found, either on the surface or in the interior of the ligament. The four circular outlines are seen on transverse section, however, but they are entirely formed of fatty tissue. What is of peculiar interest in this case is that in this fat the nerves and blood-vessels are still present.

The camel which the author had an opportunity of examining was a very young specimen, and its foot had been prepared by a fine gelatine and carmine injection. This in some measure obscured the intimate structure of the suspensory ligament. Not a trace of muscular tissue or fatty tissue could be detected either on its surface or in its substance. So complete was its transformation that not a single clue to its origin could be discovered. It is quite possible however that in a fresh uninjected specimen traces might be detected.

The suspensory ligament in these animals has undoubtedly been called into existence by the need for such a structure in the foot, and by the comparatively small value of the intrinsic muscles from which it is developed. The intrinsic muscles of the hand and foot have as their function the production of the more rapid and precise movements of the digits. In the animals which possess a suspensory ligament such a function is of no importance, whereas a powerful brace to provide against over-extension at the metatarso-phalangeal joints is an absolute essential.

But the study of the suspensory ligament of the fetlock suggests other interesting points: 1. The process of transformation of muscle to ligament appears to be effected by a fatty degeneration of the muscular fibres with a coincident multiplication of the connective tissue elements. Here, therefore, is what is usually regarded a pathological change assisting a morphological process. 2. The nerves of supply to the muscles are apparently unaffected by the change. In the sheep, in which there is not a trace of muscular tissue, they are seen in the substance of the ligament of a size relatively as great as in the ox or horse. 3. The presence of muscular tissue, where from its small amount it cannot possibly exercise any appreciable function, is peculiar. To account for its continuous existence we must of course suppose that it remains in a state of tonic contraction. The continuance of nerves in the ligament will enable it to maintain this condition.

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, September 12.—M. Wurtz in the chair.—The following papers were read:—Remarks on a memoir of MM. Lœwy and Perigaud on flexure of telescopes, by M. Villarceau.—On the comparative qualities of water of the Isère and of the Durance, as regards irrigation and provision of soil, by M. de Gasparin. He compared the constitution of the liquids at points where all the affluents were united, and at different epochs. The two rivers are closely alike as to the quality of the slime they deposit, that of the Isère being only a little more argillaceous (which slightly favours the state of suspension). Now the Durance is largely utilised for irrigation, and enriches the departments of Bouches-du-Rhône and Vaucluse especially with fertile soil; and it is suggested that a like benefit should be derived from the Isère, in Isère and Drôme.—On a new mode of exploitation of mines of sulphur, by MM. de la Tour du Breuil. They apply the principle of raising the boiling point of water by means of a dissolved salt. Chloride of calcium is so used; the bath containing 66 per cent. of it. The apparatus consists of two rectangular vessels coupled and inclined. When the operation is terminated in one, the boiling liquid is directed into the other, which is previously filled with ore. While liquation is going on (which takes about two hours) the first vessel is emptied and re-charged. One furnace suffices. The sulphur produced is very cheap (about five francs a ton) and pure. From a possible all the year, as no sulphurous acid is produced; and the extraction is very complete.—The Secretary called attention to the subscription opened for a statue to Lakanal at Foix (Ariège).—On radiophony produced by lampblack, by M. Mercadier. Not only is lampblack the best thermophonic agent at present, but it is susceptible, like selenium, of playing the rôle of the electric photophone. Instead of selenising one of the faces of his metallic double-spiral receivers, M. Mercadier covers it with lampblack, and they give good effects with intermittent solar, electric-light, and even gas, radiation. When exposed in dark to a copper plate gradually heated with an oxyhydrogen blowpipe, no sound is heard in the telephone till the plate is raised to a dull red; then it gradually increases in intensity. The author is disposed to consider the phenomenon *photophonic* rather than *actinophonic*. The resistance of these receivers diminishes as the temperature rises (from 2° or 3° to 50°), and the variation (very small) is represented nearly by a straight line.—Explanation of a curve in double circular refraction, by M. Croullebois.—On the magnetic metalls, by M. Gaiffe. He experimented with nickel and cobalt, obtained electro-chemically and variously treated before magnetising; some bars being kept hard, others annealed, and others annealed and forged. The figures show what a comparatively great coercitive force these metals (and especially cobalt) may acquire in a pure state, while pure iron, obtained by the same means, gives inappreciable deflections in the magnetometer. The annealed and forged samples produced the greatest effect (the annealed coming next). The weak coercitive force of the metals on issuing from the galvanoplastic bath, is attributed to the presence of hydrogen in combination with them.—On methylal dehyde, by MM. Henriot and Oeconomoides.—On the relative power of albuminoid substances of blood-serum, and their determination by circumpolarisation, by M. Fredericq.—On permanganate of potash employed as antidote to the poison of serpents, by M. de Lacerda. A solution of snake poison having been injected subcutaneously under the thigh of a dog, and a 1 per cent. solution of permanganate of potash a few minutes after, the latter prevented all local lesion (abscess, &c.); there was merely a very slight swelling. In other cases of injection into the veins the permanganate proved a powerful antidote.—M. Maumené communicated accounts of a new apparatus for fractional distillation, and of one for measuring the alcoholic richness of mixtures of alcohol and water.

MESSRS. MACMILLAN AND CO.'S ANNOUNCEMENTS.

IN PREPARATION.

THE ENGLISH CITIZEN

A Series of SHORT BOOKS on his RIGHTS and RESPONSIBILITIES.

THIS Series is intended to meet the demand for accessible information on the ordinary conditions and the current terms of our political life. Ignorance of these not only takes from the study of history the interest which comes from a contact with practical politics, but, still worse, it unfits men for their place as intelligent citizens. With women this ignorance frequently remains throughout life; and even with intelligent men its place is taken only by a knowledge gained in a haphazard way. The affairs of business, contact with other men, the reading of newspapers, the hearing of political speeches, may give a partial acquaintance with such matters, or at least stimulate curiosity as to special points. But such partial acquaintance with the most important facts of life is not satisfactory, although it is all that the majority of men find within their reach.

There is a large and important class who possess political privileges, and who, in the exercise of these privileges, incur arduous labour, devise intricate associations, impose upon themselves a minutely organised discipline. They, it is hoped, may find in these books information more accessible, more systematic, and perhaps more reliable, than that which is to be gained from the occasional harangues of statesmen, or from the necessarily one-sided disquisitions of the Press. They must be aware that it is on these harangues and on these disquisitions that their judgment, as a jury of citizens exercising the most august of functions, is sought; and no jury should be satisfied to learn facts only as taught them by the mouth of an advocate, however able and however learned he may be.

The Series will deal with the details of the machinery whereby our Constitution works, and the broad lines upon which it has been constructed. The volumes in it will treat of the course of legislation; of the agencies by which civil and criminal justice are administered, whether imperial or local; of the relations between the greater system of the imperial government and the subdivisions by which local self-government is preserved alongside of it; of the electoral body, and its functions and constitution and development; of the great scheme of national income and its disbursement; of State interference with the citizen in his training, in his labour, in his trafficking, and in his home; and of the dealings of the State with that part of property which is, perforce, political,—the land; of the relation between State and Church which bulks so largely in our history, and is entwined so closely with our present organization; and lastly of those relations of the State that are other than domestic.

In dealing with these questions, the aim will be not to give mere compendia of technical information, but to sum up as shortly and as clearly as possible the leading points, and to arrange these so as to shew their relation to one another, and their general bearing on the life and the duties of the citizen. The books are not intended to interpret disputed points in Acts of Parliament, nor to refer in detail to clauses or sections of those Acts; but to select and sum up the salient features of any branch of legislation so as to place the ordinary citizen in possession of the main points of the law. They are intended, further, to shew how such legislation arose, and (without going into minute historical or antiquarian details) to shew how it has been the outcome of our history, how circumstances have led up to it, and what is its significance as affecting the relation between the individual and the State. Fresh light may often be thrown upon the subject by examining the resemblance, or contrast, between our arrangements and those existing elsewhere.

The following are the titles of the volumes:

1. **CENTRAL GOVERNMENT.** H. D. TRAILL, D.C.L., late Fellow of St. John's College, Oxford. [*In October.*
2. **THE ELECTORATE AND THE LEGISLATURE.** SPENCER WALPOLE, Author of "The History of England from 1815." [*In October.*
3. **LOCAL GOVERNMENT.** M. D. CHALMERS.
4. **JUSTICE AND POLICE.** C. P. ILBERT, late Fellow of Balliol College, Oxford.
5. **THE NATIONAL INCOME, EXPENDITURE, AND DEBT.** The Taxpayer and the Ratepayer. A. J. WILSON.
6. **THE STATE AND EDUCATION.** HENRY CRAIK, M.A.
7. **THE POOR LAW.** Rev. T. W. FOWLE. [*Immediately.*
8. **THE STATE IN RELATION TO TRADE.** T. H. FARRER.
9. **THE STATE IN RELATION TO LABOUR.** W. STANLEY JEVONS, LL.D., F.R.S.
10. **THE STATE AND THE LAND.** F. POLLOCK, late Fellow of Trinity College, Cambridge.
11. **THE STATE AND THE CHURCH.** Hon. A. D. ELLIOT, M.P.
12. **FOREIGN RELATIONS.** SPENCER WALPOLE, Author of "The History of England from 1815."
13. (1) **INDIA.** J. S. COTTON, late Fellow of Queen's College, Oxford.
    (2) **COLONIES AND DEPENDENCIES.** E. J. PAYNE, Fellow of University College, Oxford.

PROFESSORS ROSCOE AND SCHORLEMMER'S CHEMISTRY. NEW VOLUME.

A TREATISE ON CHEMISTRY. By H. E. ROSCOE, F.R.S., and C. SCHORLEMMER, F.R.S., Professor of Chemistry in the Victoria University, Owens College, Manchester. With Illustrations. 8vo.

Vol. III.—ORGANIC CHEMISTRY. Part I. 21s.

Vols. I. and II.—INORGANIC CHEMISTRY. Vol. I.—THE NON-METALLIC ELEMENTS. 21s. Vol. II. Metals. Two Parts. 18s. each.

"Will deserve to rank for many years as among the best treatises on chemistry in the English language."—*Chemical Journal.*

"A series which we think may justly claim to be the best English handbook to the study of inorganic chemistry."—*Academy Review.*

"The volume just published quite maintains the standard of the two earlier ones, for it is lucid, full, and practical, and admirably illustrated."—*The Lancet.*

Now ready at all the Libraries. 3 vols. *crown* 8vo. 31s. 6d.

MR. WILLIAM BLACK'S NEW NOVEL.

THE BEAUTIFUL WRETCH: THE FOUR MACNICOLS: THE PUPIL OF AURELIUS. By WILLIAM BLACK. Author of "Madcap Violet," "The Strange Adventures of a Phaeton," "A Princess of Thule," "White Wings," &c.

LAY SERMONS. By Professor JOHN STUART BLACKIE. Crown 8vo. 6s.

ANTHROPOLOGY: an Introduction to the Study of Man and Civilisation. By E. B. TYLOR, D.C.L., F.R.S. With Illustrations. Crown 8vo. 7s. 6d.

Extract from Professor Flower's Address on Biology at the British Association.

"Within the last few months the study of our subject in this country has received an impulse from the publication of a work—small in size, it is true, but full of materials for thought and instruction—the 'Anthropology' of Mr. E. B. Tylor, the best work published in English with that title, and one very different in its scope and method from the old ethnological treatises.

"The immense array of facts brought together in a small compass, the terseness and elegance of the style, the good taste and feeling with which difficult and often burning questions are treated, should give this book a wide circulation among educated classes, and thoroughly familiarise both the word and the subject to English readers."

FRENCH HISTORY FOR ENGLISH CHILDREN. By SARAH BROOK. With Coloured Maps. Crown 8vo. 6s.

"Miss Brook has succeeded admirably. . . . Her book is lucidity itself; she has neglected, so far as we can judge, no fact that was worth noting . . . though she writes invariably with praiseworthy self-restraint, she has made her book attractive as well as instructive . . . more advanced students may read the book with pleasure, and even use it for purposes of general reference."—*The Times.*

NATURE SERIES. NEW VOLUME.

FASHION IN DEFORMITY, as Illustrated in Customs of Barbarous and Civilised Races. By W. H. FLOWER, LL.D., F.R.S., &c. With Illustrations. Crown 8vo. 2s. 6d.

"Professor Flower's volume is as interesting as it is instructive."—*St. James's Gazette.*

NOTES AND THOUGHTS ON GARDENS AND WOODLANDS. Written chiefly for Amateurs. By the late FRANCES J. HOPE. Edited by ANNE J. JOHNSTONE. Crown 8vo. 6s.

"We heartily welcome this book, which treats not only of gardening, but of plant lore in general, in a loving and suggestive way."—*The Graphic.*

FIRST LESSONS IN PRACTICAL BOTANY. By G. T. BETTANY, M.A., F.L.S., Lecturer in Botany at Guy's Hospital Medical School. 18mo. 1s.

"This is an excellent little book. Its diligent study by teachers as well as pupils would give descriptive botany the educational value which is so often claimed for it."—*Nature.*

NEW TESTAMENT IN THE ORIGINAL GREEK. The Text Revised by B. F. WESTCOTT, D.D., Regius Professor of Divinity, Canon of Peterborough, and F. J. A. HORT, D.D., Hulsean Professor of Divinity, Fellow of Emmanuel College, Cambridge: late Fellows of Trinity College, Cambridge. 2 vols. crown 8vo. 10s. 6d. each.

VOL. I. TEXT. VOL. II. INTRODUCTION AND APPENDIX.

"This work, formed exclusively on documentary evidence without reference to any printed text, has been long expected by scholars. It is probably the most important contribution to Biblical learning in our generation. The revisers, it is understood, had the advantage of consulting it during the progress of their work."—*Saturday Review.*

EDMUND WHEELER,

482, Tollington Road, Holloway, N., London.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

The WINTER SESSION of 1878-9 will commence on October 1, when an Introductory Address will be delivered by Dr. Bernays, Ph.D., F.C.S., &c., at 3 P.M.

Two Entrance Science Scholarships of £100 and £60 respectively, open to all 1st Year's Students, will be offered for competition. The Examination will be held on the 5th, 6th, and 7th of October, and the Subjects will be Chemistry and Physics, with either Botany or Zoology at the option of Candidates.

Special Classes are held throughout the year for the "Matriculation," "Preliminary Scientific," and "First M.B." Examinations of the University of London.

All Hospital Appointments are open to Students without extra charge. Scholarships and Money Prizes of considerable value are awarded at the Sessional Examinations, as also several Silver and Gold Medals.

The Fees may be paid in one sum or by instalments. Special Entries may be made to Lectures or to Hospital Practice, and special arrangements are made for Students entering on their Second or subsequent years; also for Dental Students and for Qualified Practitioners.

Several Medical Practitioners and Private Families residing in the neighborhood receive Students for residence and supervision, and a Register of Inspected and Approved Lodgings is kept in the Secretary's Office.

Prospectuses and all particulars may be obtained from the SECRETARY, Dr. GILLESPIE.

W. M. ORD, M.D., Dean.

ST. THOMAS'S HOSPITAL, ALBERT EMBANKMENT.

UNIVERSITY OF LONDON MATRICULATION AND PRELIMINARY SCIENTIFIC EXAMINATIONS.

The Special Classes in the Subjects for the above Examinations will be recommenced at St. Thomas's Hospital Medical School on Monday 11th, and Tuesday 12th October, respectively.

The Preliminary Scientific Instruction forms the best preparation for the Entrance Science Scholarships, value £100 and £60, awarded annually in October.

Prospectus and all particulars from the Secretary, Dr. GILLESPIE.

W. M. ORD, M.D., Dean.

NORMAL SCHOOL OF SCIENCE AND ROYAL SCHOOL OF MINES.

The following LECTURES will be given in the SCIENCE SCHOOL, at South Kensington:—

BIOLOGY.—Professor Huxley, F.R.S., will commence his course of lectures on Monday, October 20, at ten a.m.

CHEMISTRY.—Dr. Frankland, F.R.S., will commence his course of lectures on Monday, October 20, at twelve noon.

METALLURGY.—Professor W. Chandler Roberts, F.R.S., will commence his course of lectures on Monday, October 20, at ten a.m.

PHYSICS.—Professor Guthrie, F.R.S., will commence his course of lectures on Monday, October 20, at ten a.m.

The respective laboratories were opened on the 3rd instant, at ten a.m.

The prospectus and full particulars may be obtained on application to the REGISTRAR of the Normal School of Science, South Kensington.

BEDFORD COLLEGE (FOR LADIES),

8 AND 9, YORK PLACE, PORTMAN SQUARE, LONDON.

The SESSION will begin on THURSDAY, October 17th.

A Course of Lectures on Logic will be given by W. C. Coupland, M.A.

Prospectuses, with full particulars of Scholarships, Boarding, &c., may be had at the College.

F. KENSINGTON, Hon. Sec.

INSTRUCTION IN MATHEMATICS.

STUDENTS wishing for Assistance in

Mathematics can be attended at their own homes by a Cambridge Graduate, M.A., F.R.S., on very moderate terms. Address O. P., 16, Swakeley Terrace, Shepherd's Bush, W.

"As we have often laboured to show, Harvey did not, as a matter of history, discover the circulation."—*The Lancet*, August 23, 1851.

PROFESSOR OWEN and VIVISECTION.

Readers of his address on unveiling the statue of Harvey at Folkestone, on the 8th ult., and of the "Life of Hunter" in the new edition of the "Encyclopædia Britannica," are invited to peruse the pamphlet on Harvey, and correspondence with Professor Owen on "Hunter and Assurism," which can be obtained gratis by sending a penny stamped and directed wrapper to GEORGE R. JESSE, Honorary Secretary and Treasurer, Society Abolition Vivisection, Henbury, near Macclesfield, Cheshire.

September 20, 1878.

A DICTIONARY OF MUSIC AND MUSICIANS.

BY EMINENT WRITERS, ENGLISH AND FOREIGN,

EDITED BY GEORGE GROVE, D.C.L.

Vols. I. and II.—Price 21s. each.

Vol. I. A to IMPROMPTU. Vol. II. IMPROPERIA to PLAIN SONG.

Demy 8vo, cloth, with Illustrations in Music Type and Woodcut. Also published in Quarterly Parts. Parts I. to XIV. now ready, price 3s. 6d. each. Cloth Cases for binding Vols. I. and II., price 1s. each.

TO BE COMPLETED IN THREE VOLUMES.

"Dr. Grove's Dictionary will be a boon to every intelligent lover of music."—*Saturday Review.*

"What is modestly called a 'Dictionary' might have fairly been entitled an 'Encyclopædia,' for the editor has included in his scheme everything that belongs to music, or is allied, or is even distantly related to it. It would be a great mistake to regard this work as useful only for the purposes of reference. It is a collection of interesting and valuable articles on all kinds of musical subjects, which amateurs, who take a genuine interest in the art they profess to love, will read from beginning to end."—*Daily News.*

"We now take leave of this 'Dictionary,' recommending it heartily to our readers as full of instruction and amusement."—*The Times.*

"What will strike the reader first of all, perhaps, is the fulness and completeness of the information here collected."—*Examiner.*

"As a complete account of the biographical as well as technical materials relating to the art of music and its history, Mr. Grove's Dictionary is without precedent in England."—*Quarterly Review.*

"The work, when complete, will supply a want which has long been felt by amateurs and professors of the art in this country."—*Illustrated London News.*

"This work promises to be for music what the best encyclopædias are to general literature and science."—*Guardian.*

"The excellence of the dictionary becomes more and more conspicuous as the work goes on."—*Daily Tribune* (New York).

NORTH BRITISH AGRICULTURIST

is the only Agricultural Journal in Scotland, and circulates extensively amongst Landed Proprietors, Factors, Farmers, Farm-bailiffs, and others interested in the management of landed property throughout Scotland and the Northern Counties of England.

The AGRICULTURIST has also a very considerable circulation on the Continent of Europe, America, Australia, and the Colonies.

The AGRICULTURIST is published every Wednesday afternoon, in time for the evening mails, and contains Reports of all the principal English and Irish Markets of the week, besides Telegraphic Reports of those held on the day of publication.

The Veterinary Department is edited by one of the leading Veterinarians in the country, and is invaluable to the breeder and feeder as a guide in the rearing of animals, and their treatment when labouring under diseases.

Full Reports are given of the Meetings of the Royal Agricultural Society of England, the Royal Agricultural Society of Ireland, the Highland and Agricultural Society of Scotland, the Scottish Chamber of Agriculture, and all the principal Agricultural Associations throughout Great Britain and Ireland.

For Advertisers addressing themselves to Farmers a better medium does not exist.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 15s.

Office—377, High Street, Edinburgh.

Post-Office Orders payable to Charles Anderson, Jun., Edinburgh.

AUSTRALIAN ABORIGINES

Australian Aborigines: the Languages and Customs of several Tribes of Aborigines in the Western District of Victoria, Australia. By James Dawson. (Melbourne: Robertson; London: Macmillan and Co., 1881.)

MR. DAWSON, a settler of old standing in the district west of Melbourne, and his daughter, Mrs. Taylor, who has been familiar from childhood with several native dialects, have in years of careful inquiry collected the present volume of information as to the languages and life of the group of tribes living inland from the coast between Portland Bay and Cape Otway. These tribes form part of the native population described in the "Aborigines of Victoria," compiled by Mr. Brough Smyth for the Victorian Government; but able and extensive as that work is, the anthropologist sees on comparing it with the present volume how far he must still be from thoroughly understanding the native institutions, when a minute study of one district can bring out so many new and difficult points as are to be found here. Take the native marriage laws as set down by Mr. Dawson. The tribes are split up into totem-classes named after animals, both sons and daughters belonging to the mother's class, and not being allowed to marry within it; thus a Pelican youth may not marry a Pelican girl, or a Boa youth a Boa girl, but Pelican may marry Boa. So far, this is like the exogamous rules found in various other parts of the country; but here it is further stated that though the class follows the mother's side, the tribe itself follows the father's side, and the natives are not allowed to marry into their own tribe either, nor may a man marry into his mother's or grandmother's tribe, nor into an adjoining tribe, nor into one that speaks his own dialect. This remarkable set of restrictions, which does not seem to correspond exactly with those of any other district in the world, is considered by the tribes who live under it as intended to prevent marriage between those of "one flesh," and indeed it bars kin-marriage in both the male and female line in a more thorough way than the known laws of any other Australian tribes. No marriage or betrothal is permitted without the approval of the chiefs of each party, who first ascertain that no "illegal" relationship exists. Any symptoms of courtship between those of "one flesh" are put down by rough handling of the culprits, and parents are apt to save their children from breaking the law by betrothing them in proper quarters as soon as they can walk. What can have been the motive which led the ancestors of these savages to carry their prohibited degrees to an extent which our physicians would consider practically absurd? Mr. Dawson speaks of these laws as admirable, and plainly thinks them founded on practical reasons against marrying-in, for he says that where the prohibitions have been disregarded under European influence, the aborigines attribute to this disregard the greater weakness and unhealthiness of their children, and the increase of insanity. This, however, may have got into the native mind from hints by the white doctors, and the whole subject of these marriage-prohibitions is as yet an unsolved problem. This is better seen when one does not look at one particular point, but at the system as a whole, with its network of ceremonial regulations. Among these, the custom of avoiding the mother-in-law is of course described by Mr. Dawson. He gives the usual details how, when a girl is betrothed, her mother and aunts may not look at or speak to the man for the rest of his life, but if they meet him they squat down by the wayside and cover up their heads, and when he and they are obliged to speak in one another's presence, they use a peculiar lingo, which they call "turn-tongue." This queer dialect is not used for concealment, for everybody understands it, and some examples of it are here given which show that it has much in common with the ordinary language. Should the present notice meet the eye of Mr. Dawson, it may be suggested that it would be worth while to find out whether the "turn-tongue" is an old-fashioned dialect kept up for this ceremonial purpose. For the rest of the marriage-customs we must refer to the book itself; but to give an idea of the state of formality into which life has come among these supposed free-and-easy savages, mention may be made of the duties of the bridesmaid and groomsman. When the married pair have been taken to the new hut built for them, for the next two moons the groomsman and the husband sleep on one side of the fire, the bridesmaid and the wife on the other, the new-married couple not being allowed to speak to or look at one another. The bride is called a "not-look-round," and the pair in this embarrassing position are a standing joke to the young people living near, who amuse themselves by peeping in and laughing at them.

Among the interesting questions as to Australian arts and ideas which Mr. Dawson touches on, is whether they had any notion of boiling food. He confirms the general opinion that they had not, and states that there is no word meaning to boil in their native dialects. But it does not always follow that what is true as to one group of tribes is true everywhere. Mr. Brough Smyth gives an account of the fish-hooks of the aborigines in Victoria, but Mr. Dawson declares that in his district they were unknown, though the native fishermen have come so near angling as to use a rod and line with a bunch of worms for bait, with which they pull out the fish before he has time to disgorge. Looking over the grammatical part of the book, we find the list of numerals in the native dialects one of the most perfect examples of the way in which numerals have been developed from counting on the fingers. They say "one hand" for 5, "two hands" for 10, and so on with hands and twenties up to 100. But the unusual and noticeable point is, that though getting so far, they have not worked out words for the intermediate numbers above 10, but fall back on the primitive gestures; thus they have not words for 11 or 12, but they say 10, and hold out one finger or two to make up the number. Mr. Dawson seldom quotes or criticises books, but when he gives the fact that there is a native word for 100 he adds a note that this is wholly at variance with the statement made by Mr. E. B. Tylor ("Primitive Culture," vol. i. p. 220) as to some Australian tribes having no numeral words even so high as 5. To prevent misunderstanding he should have pointed out that the next page of the work in question makes reference to other

Digitized by Google

Australian tribes reported to have numeral words up to 15 or 20. But the point raised is well worth attention. The statement as to tribes in various districts having no distinct numeral words above three, and only struggling on to four and five by saying "two-two," &c., rests on the authority of Europeans who have studied the native languages, sometimes well enough to write grammars of them. Are we to think that the natives generally had words for large numbers, and yet the Europeans failed to discover them? Or, rather, is it not easy to suppose that some tribes raised themselves (possibly since contact with the white man) above this low level of arithmetic, making, out of their counting on the fingers, numeral words even as high as the words here given for 100? It would be interesting if it could be shown etymologically that the terms here given for 20 and 100 had originally a material meaning, like the word for 5, which still means "hand."

One of the greatest difficulties in studying savages is to know how far to trust or distrust their assurances that what they tell is really their own, and not picked up from foreigners. From this point of view it is worth while to look closely at the story of the lost Pleiad, which here appears among the native myths of the "black-fellows." The author's friends naturally doubted its genuineness, but on further inquiry it was found to be widely known. The tradition is that the Pleiades were a chiefess called Gneeanggar and her six attendants; Waa, the Crow (the star Canopus), fell in love with her, and finding that she and her women were going in search of white grubs, he turned himself into one, and bored into the trunk of a tree, where they were sure to find him. The women, one after another, poked their little wooden books into his hole, but he broke the points, till at last his love put in her beautiful bone hook, and he let her draw him out, whereupon he turned into a giant and ran away with her; since then only six Pleiads—the serving-women—have been left. Now between this story and our classical myths there is a difference. Ovid's version seems to carry its origin on its face, agreeing with the fact that only six of the stars in the cluster are bright and plain to common eyes, so the myth tells of a hidden or faint seventh. She is Merope hiding herself for shame at marrying a mortal, or Electra putting her hand before her eyes, not to see the ruin of Troy. But in the Australian tale the vanished star, being the queen, ought of course to be the brightest; so that there is little sense in the story, unless Mr. Dawson is prepared to maintain that the Australians remember a time when there was a Pleiad brighter than the rest, which has now vanished. It would be easier, if more commonplace, to guess that the natives got the idea of a lost Pleiad from some Englishman who had heard the story at home, but missed the point of it.

The anthropological work done by Mr. Dawson and Mrs. Taylor hardly needs praising. It is enough to point out how carefully, not relying on books, they have made their own inquiries on every subject, and recorded them as scientific material. It is to be hoped that they will not cease their researches, for there must still be much valuable evidence to be gleaned in their district, if it is done without delay.

EDWARD B. TYLOR

OUR BOOK SHEL

A Dictionary of Chemistry and Allied Watts, F.R.S. Third Supplement. Longmans, 1881.)

We have no publication in English stri to *Liebig's Annalen* or the *Annales de C* and were it not for this now gigantic mistry by Mr. Watts many, both advan students of our science, would find siderably increased by the necessity of a great number of facts and records foreign journals. The chemical recor includes discoveries made in 1880, a number of exhaustive articles by Profe on Isomerism; G. C. Foster, on T Schuster, on the Spectrum; Thorpe, on and others. This part commences with articles being Gallium and Gases, the complete and up to date. A long sect Heat, which, with the article on Therm valuable. In the portion on Isomerism to notice a slight but still important def restriction of the term isomeric. That only be classed as isomeric when their re that they are of the same type of structu is of some length, and contains the ma hypotheses brought forward by Van 't and others. We thoroughly agree with paragraph of the article, and venture to a when we do know a little about the laws o in the case of reacting molecules the term unsaturated atoms will cease to be employ dovetails into the one on Light, and toget important fraction of the book. The grea volume is of course taken up by "organic chemistry, a considerable number of min being however described, the section on th to yttrium being very interesting. The re original papers attached to each article rend more valuable to those chemikers and phy a few languages is no difficulty. Although it is very thick, and probably an index w the search after any particular description is a minor one.

The Madeira Earth-electric Cloud

What a valuable paper, Mr. Editor, you have week from Mr. J. B. N. Hennessey, with its diagr set of sun-spots which broke out suddenly near the sun's disk, between 4h. and 5h. p.m., on July 25 by the photo-heliograph of the Indian Trigonom under his able charge, at Dehra.

His enthusiasm at having localised the appea phenomenon in time, as well as space, is unreserv his long experience as an observer gives his opinion weight, when he further holds forth on the rarity occurrence, on such a scale and so centrally situated disk—whence its probable vast importance for the earth and the foundations of a new science. All th ably true and suggestive for the future; but meanw to claim the first fruits of the case as the very thing expecting ever since I left Madeira at midnight on Ju

And why should I have been expecting such an ou do you ask? Well, do you remember my letter f

Digitized by Google

Madeira on June 27 (NATURE, vol. xxiv. p. 212, with a sequence on p. 237) describing the extraordinary cloud that appeared there on June 26, alarming all the inhabitants, the typically "oldest" of whom declared they had never seen such a cloud as that before? It was, too, in very truth a most remarkable affair; and seemed to me only to admit of full explanation as a peculiar case of the earth answering by escape of its interior electricity to the sun; where, according to my own daily solar diagrams, there had just occurred an outburst of solar spots very nearly over the ends of the solar radii that were then pointing towards the earth.

Weeks passed on without anything to interfere with, or undervalue, that explanation; when lo! on July 26 (the very same day, curiously enough, of the next month) another cloud appeared over Madeira, of just the same peculiar physical character as that of June 26. "Why," were inclined many visitors to ask, "is this kind of cloud, in spite of the asseverations of the 'oldest' inhabitants, no very great rarity after all in this part of the world?" There had been certainly thus two cases of it occurring with a very short interval between them; but nevertheless, I was inclined to respect the assertions of the greybeards; and said, "Something unusual must again have happened in the sun; but as my observatory was dismantled on July 23, and the component parts of it packed up ready for shipment on July 25 and 26, I had not then any knowledge of what it might be." Now, however, see how perfectly Mr. Hennessey's Indian solar photographs fulfil all that was required to make this second Madeira cloud phenomenon an exactly similar cosmical case to that of its mensual predecessor; or to testify that an extraordinary, unusual, most sudden outbreak of solar spots did take place over the very part of the sun's surface turned towards the earth late on July 25, and within twenty-four hours afterwards the earth-electric cloud made its appearance above Madeira, where it was thus noted in my pocket journal:—

"Tuesday, July 26.—During this afternoon there was a great cloud-structure formed to the west, with all the characteristics of smooth-rimmed lenticular strata under strata, and the topmost visible one breaking out into fringes of cirro-cumulf, that marked the still grander cloud of June 26." This one was however very splendid after sunset, and when the red tints thereof had faded from it they were replaced by the richest and purest browns, of the burnt-umber variety, I have ever beheld in the sky. The cloud was vertical over the lower southern slopes, almost the southern sea-shore of Madeira; not over the high peaks of the island, in so far at once pointing to a different origination from Dr. Muirhead's (of Cambuslang) cloud in NATURE, vol. xxiv. p. 237. That cloud was an affair plainly of the cold of a snow-covered mountain-top in Britain, and is just such an ordinary local production as any one can see for a large part of the year on the South African hills round about Table Mountain and Table Bay—whenever the south-east trade-wind blows over that country. For there, day after day, it produces very clumsy-shaped masses of vapour either on, or vertically over, the tops of the hills, according to their respective absolute elevations. But never once, during ten years, did I see any approach in the arrangement of the constituent particles of those clouds to the neat, refined, peculiar shapes of what formed the most conspicuous characteristic of the two successive Madeiran earth-electric clouds of June 26 and July 26. They had each been preceded by as peculiar, as rare, a central outburst of solar activity, and probably required no less for their due manifestation, as well as the performance of their functions in cosmical electric radiations and exchanges.

American Cretaceous Flora

I HAVE only just read Prof. Newberry's clear and concise account of the American Cretaceous series (NATURE, vol. xxiv. p. 191). I regret that I am still unable to agree with him that the relative ages of American and European Cretaceous beds are satisfactorily correlated. I should not again venture to insist so strongly on what must seem to Dr. Newberry to be but an individual opinion, except that he seems to expect a reply, and I have further some new evidence to bring forward. Of my opinions the one to which he takes most exception seems to be that "no American or European so-called Cretaceous land flora can be proved to be as old as our White Chalk." It is this statement therefore which I must substantiate.

In America the plant-beds of Vancouver's Island contain many Angiosperms, and are said to be of the age of the Gault or Upper Greensand, and the Dakota group, which has yielded one hundred distinct species of Angiosperms, is said to be older than our Chalk. The Colorado group is said to represent not only our Grey and White Chalk, but the Mästricht beds. Even the Laramie group or "Lignite series" is placed in the Cretaceous system. I have unfortunately not the books requisite to re-examine critically the American evidence, and must therefore confine myself to stating that which on this side of the Atlantic tends to show the relative age of the American series to be very considerably overestimated. I would propose, however, to Prof. Newberry an exchange of the more abundant Cretaceous mollusca, in order that they may be compared together; after which I might possibly find myself able to visit some of the American sections. This I should the more like to do, as I happen to be acquainted both with the Cretaceous and Eocene mollusca, and with the floras, of England—the very evidence, in fact, upon which the respective ages of the series is to be decided.

In the first place I am able to assure Prof. Newberry most positively that on plant evidence the Laramie series must be bracketed, if anywhere, with our Middle Eocene. Not only is the facies of the flora identical, but identical species appear in both continents in these series. I cannot yet give a list, but I would particularly point to such highly characteristic species as *Lygodium Kaulfussi*, Heer (syn. *L. neuropteroides*, Lesq.), and *Anemia subcretacea* (Saporta) (syn. *Gymnogramma Haydenii*, Lesq.), which were identified by Lesquereux himself after comparison with actual specimens which I forwarded to him. These are fully described in the Palæontographical Society's publications, which I hope Prof. Newberry will glance through. We have beyond all question, in the first stage of the great "Lignite series," a common line to work from, and the age of this line is, assuredly, according to the plants, that of our Middle Bagshot series. Below our Middle Bagshot there is, in France and England, a vast series of Eocene deposits containing many distinct floras of most dissimilar types, and about which, in many cases, scarcely anything is known. Even at the base of these we are very far from the age of our Chalk, we have still an obscure series of local deposits which to some extent bridge the gap between our Secondary and Tertiary periods. Some of the most noted of these deposits I have recently visited.

The highest, I believe, of these so-called Cretaceous beds in Europe is the coral deposit of Faxoe. Its solitary claim to be considered of Cretaceous age is a *Pleurotomaria!* It has no Cephalopods except *Nautilus* and *Aturia zic-zac*, and not even the persistent *Inoceramus*. Except Pleurotomaria, the mollusca are all more of Eocene than Cretaceous type. *Cypræas* are abundant, and there is a *Mitra*, *Triton*, *Voluta*, *Turbinella*, a *Rostellaria* and *Ampullaria*, &c.

In the underlying "Faxoelaget" the Cretaceous element is reinforced by *Baculites* and *Scaphites*. In the Greensand of Bornholme, *Belemnites* and *Inoceramus* are added; and finally, in the Chalk of Moen, a smooth *Ammonite*, one or more large *Hamites*, and a variety of other Cretaceous types appear. We have thus a clear passage downward into the Cretaceous series; but even the age of the Moen's Chalk is not quite definitely known, for the supposed *Belemnitella*, which apparently fixed its zone, is in reality a *Belemnite*. A few forms, however, seem to link it slightly with the Greensand of Aachen, whose age I shall now consider.

The highest of the Aachenian series is Chalk with flints. In this mollusca are few; but this is of less importance, since the Chalk rests upon Greensand, in which they abound. The fossils are in much the same condition as at Blackdown, and among them are about sixteen apparently Gault and Blackdown species. The greater part of the latter are however carried up into four Grey Chalk, where they cease simply, as far as we know, because the succeeding beds were not fitted to preserve them. These shells are mixed with others, about thirty species, of Tertiary aspect, including *Voluta*, *Murex*, *Turbo*, *Fusus*, *Pyrula*, *Borsonia*, *Bulla*, *Turritella*, *Corbula*, *Tellina*, *Cytherea*, *Lucina*, *Pectunculus*, &c., and *Clavagella*. The presence of *Bellemnitella mucronata* and *B. quadrata*, together with *Baculites*, also point to its being at least younger than the Lower Chalk. Below these are the sands with Dicotyledons. The flora these contain, while mainly unlike that of the Eocene, possesses nevertheless some types of leaves which appear identical with Eocene forms, and is of the highest importance in comparing the American

Digitized by Google

Cretaceous series. I need not refer to the Mästricht beds, except to notice that a mixture of Tertiary and Cretaceous types of mollusca is also apparent in them. One circumstance, however, lessens the value of the evidence presented by the mollusca and the flora; we are so little acquainted with either the Gastropods, the Dimyaria, or the plants of the White Chalk age, that it is possible these may have inclined more to Tertiary types than those of the Grey Chalk would lead us to suspect.

I believe that in the American Cretaceous molluscous faunas there is precisely the same mingling of types described above, and if so, they should surely be bracketed together, rather than with our Neocomian Gault, or even Grey Chalk, which present no such mixture and contain few Tertiary types, except in unimportant groups, as Dentalium. Further, we must not overlook the oft-repeated negative arguments that we have no dicotyledonous plants of these ages in Europe, and that *Baculites*, &c., may have survived longer in America than in Europe. The whole series in America forms, so far as I gather, a natural sequence, the age of one part of which, the Laramie, can be fixed as Middle Eocene, and I think, before correlating the remainder with the older Cretaceous beds of Europe, with which neither their fauna nor flora agrees, the position occupied in the American series by the older Eocene, and the transition beds which I have enumerated, should be as far as possible ascertained. The matter is thus still, and must remain for the present, in an unsatisfactory state; but the importance of removing all doubt as to the relative position of those American beds which have yielded such magnificent palæontological data, and of the more typical British strata, is so great that I hope Prof. Newberry will not let the subject drop.

J. S. GARDNER

Gradations between Hermaphroditism and Gynodiœcism

ABORTION of the stamens in some portion of the flowers occurs in different species of the genus Dianthus. *D. superbus* has been shown to be gynodiœcious in my work on "Alpenblumen" (p. 202, Fig. 79). *D. deltoides*, the only species growing near Lippstadt, has lately been examined by myself, and has been found under certain circumstances to become gynomonœcious and gynodiœcious. Of *D. Carthusianorum* among 167 flowering stalks sent me from Thuringia by my brother, Wilhelm Müller, there were two producing female flowers with greatly aborted stamens. *D. deltoides* near Lippstadt offers interesting gradations from hermaphroditism to gynodiœcism. On the border of a meadow of some hundred stems examined by myself, all flowers, without exception, proved proterandrous, with normal development of anthers and stigmas. In the grass-grown slope of a sandy hill ("die Weinberge") likewise all stems produce proterandrous flowers, but on many stems the stamens, although emerging above the petals before the development of the styles and stigmas, bear diminished whitish anthers not opening at all, and containing only some shrivelled pollen grains. Lastly, in a barren sabulous locality ("Schützenplatz") many of the stems produce female flowers, with stamens aborted in the same degree as shown in *D. superbus* ("Alpenblumen," Fig. 79D), and not unfrequently such female flowers and proterandrous hermaphrodite ones are found on the same stem.

Lippstadt HERMANN MÜLLER

Red Stars

DR. DOBERCK, who has paid particular attention to colour in his observations of Doubles, has kindly sent me the following list of red stars found by him in 1880. The first column gives the number, and the second and third the positions (for 1855) in the B.D. :—

No.	α h. m.	δ ° ′	Colour.	Date in 1880.
+ 4°877	5 7	4 59	Red	Jan. 30
*	3 12	±64	Glowing red	Feb. 8
5°1790	7 40	5 46	Ruddy	,, 14
20°1775	7 13	20 42	Pale red	,, 14
22°1198	6 1	22 13	Pale red	,, 14
26°2250	11 37	26 2	Red	March 8
33°4456	22 6	33 53	Red, but very pale	Sept. 10
20°5386	23 45	20 51	Pale red	,, 10

* Dr. Doberck does not give the number of this star, but it seems to be, probably, 64°391.

Dr. Doberck remarks that the two stars on both sides of ε *Leonis* are pale red; and in *Coma Ber.* and south of it are two ruddy stars. J. BIRMINGHAM

Millbrook, Tuam, September 18

Bombay Rainfall and Nile Floods

IN looking over data of the rainfall at Bombay and comparing them with the ebb and flow of the Nile for the corresponding years from 1849 to 1880 inclusive, I was so struck with the similarity, almost identity, of magnitudes, that I have been induced to copy them out, and perhaps you may consider them worthy of publication in your most valuable journal. Within a trifling fraction the whole of the annual rainfall at Bombay happens in the months of June, July, August, and September. Very rarely a little falls in May, perhaps a little more frequently, some in October, but these small quantities but slightly augment the annual total. They are included in the four months' totals in the following table :—

Year.	Rainfall of June and July in Bombay.	Ditto June, July, and August in Bombay.	Ditto June, July, August, and September in Bombay.	Variation from mean atmospheric pressure.	Lowest ebb of the Nile.	Highest flood of the Nile.	[illegible]
	inches.					feet.	
1849	74·5	88·16	118·88	−·011	1·64	22·31	[illegible]
1850	36·5	43·11	51·15	−·001	1·64	18·47	[illegible]
1851	77·7	101·3	106·14	−·013	1·8	23·13	[illegible]

1877	51·99	55·9	70·96	+·037	−1·96	16·8	
1878	73·73	95·63	123·1	−·011	−·72	26·18	
1879	36·95	66·22	73·41			25·03	
1880	38·79	43·55	71·23			21·45	

The floods of the Nile are mainly caused by the heavy rains which descend upon the high tablelands of Abyssinia, a range of mountains on the opposite side of the Indian Ocean to that of the Ghauts, but parallel to them and under the same latitude. The inference to be drawn is obvious. The great south-west monsoon which sweeps over the Indian Ocean in the summer months produces a like effect in both cases, inducing fertility and plenty, alike on the plains of the Concan of India and the Delta of Egypt. It may be mentioned that the lowest ebb of the Nile always happens in June, and the highest flood about the end of September and the beginning of October. I have included in the table a column showing the variations of the mean barometrical pressure, and a column giving Wolf's observations of sun-spots, taken from NATURE, vol. xxi. pp. 477–82.

THE INTERNATIONAL EXHIBITION AND CONGRESS OF ELECTRICITY AT PARIS[1]

II.

THE most crowded place in the Exhibition is the *Théâtre de l'Opéra*. Here from eight to eleven on three evenings in the week are to be seen four long *queues* waiting for their turn to enter one of the four rooms where the mysterious music is to be heard. Round the walls of each room are hung telephones in pairs, some twenty pairs in all, and the same number of persons are admitted. On putting the telephones to your ears you hear the music which is being performed at the opera-house more than a mile distant. Some of the singers seem to be on your right hand, others on your left, and it sometimes happens that a particular voice is quite piercing in its loudness. There are in fact ten transmitters disposed along the front of the stage, near the footlights, and ten wires leading from them, two of which are connected with the telephones intended for your two ears. Special precautions are taken to prevent the action of the transmitters from being disturbed by the tremors of the boards under the feet of the actors, the transmitters being supported on india rubber and loaded with lead. The telephonic apparatus employed is that of the Ader system.

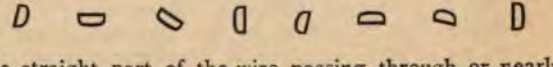
The greatest novelty as regards principle is exhibited in Dolbear's telephone, in the United States department. The receiver has no magnet, but has two parallel metallic plates near together, and electrically insulated from each other. One of them is connected with the line wire, and the other (in the specimen here exhibited) with the return wire. These two wires are connected with the terminals of the secondary coil of a small Ruhmkorff at the sending station; and the voice of the speaker produces variations in the primary current, on the usual plan of varying the resistance in the circuit of a local battery by variations of pressure. The secondary circuit is not completed, inasmuch as the two plates do not touch; but the opposite electricities which are transmitted to them attract each other on electrostatic principles, and the plates are thus made to vibrate in unison with the voice of the speaker at the sending station. The instrument exhibited is very effective, and reproduces a whisper with greatly increased intensity. It is claimed that this invention does away with the disturbance experienced in other telephones from currents in neighbouring wires, inasmuch as such currents will not affect the attraction between the plates. We should add that the instrument exhibited speaks fairly even when the plate next the ear is disconnected from the wire intended for it, but of course less loudly than when the connection is made. This is just what one would expect from electrostatic attraction, the attraction of a charged for an uncharged body being less than that between two bodies oppositely charged.

We have had an opportunity of seeing the system adopted by Mr. Edison for the measurement of the quantity of electricity consumed in each house which receives a supply from one of his mains. A definite proportion (one thousandth part) of the whole current which goes through the house is shunted through a cell containing two copper plates in a solution of sulphate of copper. The positive plate loses, and the negative plate gains, an amount of copper exactly proportional to the quantity of electricity which passes. There are two such cells in series, one serving as a check upon the other, and the whole arrangement is kept under lock and key, to be opened only by Mr. Edison's agents when they come round to inspect the meters. As the lamps supplied (of a given type) are almost precisely alike in their resistance, and the current, when flowing, is always nearly the same, this arrangement gives a practically accurate measure of the illuminating power supplied.

Much interest has been excited by the exhibition of three magneto-electric machines constructed by Prof. Pacinotti of the University of Cagliari. One of these, constructed at Pisa in 1860, is the earliest example of the principle of the ring-shaped armature, since embodied in the machines of Gramme and Brush. It was originally constructed as an engine to be driven by a current from without; but it was also used as a generator of electricity, and both these uses of it were described in a paper in the *Nuovo Cimento* in 1864. The machine contains an iron ring like an anchor ring, round successive portions of which are wound coils of insulated copper wire in depressions cut in the ring to receive them. The intervening portions of the ring are thus (as in the Brush machine) enabled to come very nearly into contact with the surrounding fixed magnets. These consist of two half rings which are the pole pieces of two straight electromagnets. The coils above mentioned are connected in a series, and their junctions are in connection with the several segments of a commutator, as in the Gramme machine.

The second machine was constructed in 1873, and described in the *Nuovo Cimento* in 1874. It is a generator of electricity, of the kind now known as the shunt dynamo, that is to say, the current generated is divided in parallel circuit between the fixed electro-magnet and the external resistance. This is done by means of two pairs of brushes making contact with different sections of the revolving commutator. The ring is replaced by a flat cylinder, across which the successive coils are wound in depressions made for the purpose, the directions of winding being the same as in Siemens' continuous current machine, which was invented about the same time. The connections of the successive coils with one another and with the segments of the commutator are the same as in the first machine.

The third machine, which was constructed in 1878 on a model dating from 1875, is of a type of which, so far as we know, it is the only example. The idea of it is taken from the well-known experiment (Arago's rotations) in which a revolving horizontal copper disk causes a large magnetised needle balanced above it to revolve in the same direction. The explanation of the effect was first given by Faraday. It depends on the action of a current generated in the copper disk by its motion in the magnetic field due to the needle. The strongest current flows along that diameter which is parallel to the needle, and the current is completed through the circumferential portions of the disk. Pacinotti virtually cuts away all except the diametral portion and one of the two circumferential portions; in other words, he takes a wire and bends it into the shape of the letter D. This is one convolution of his revolving coil; the next is like the same D tilted a little; the next is tilted a little more, and so on; so that some of the convolutions have the positions—



the straight part of the wire passing through or nearly through the axis of the coil, and the curved part being in the circumference. There is no room for a core in the ordinary sense, as the wires occupy nearly the whole interior space; but pieces of iron are so disposed partly within and partly without the coil as to serve the purpose of a core, by increasing the induction of the fixed magnets.

(*To be continued.*)

ILLUSTRATIONS OF NEW OR RARE ANIMALS IN THE ZOOLOGICAL SOCIETY'S LIVING COLLECTION[1]

IV.

8. *THE White-nosed Saki* (*Pithecia albinasa*).—The peculiar American monkeys which belong to the closely-allied genera *Pithecia* and *Brachyurus* of naturalists, and are generally known as "Sakis"—a name probably derived from some Indian term—are restricted to the forests of Guiana and Amazonia, and seem to have in the case of each species a very restricted geographical area of distribution, one of these monkeys not intruding within the limits of another. As regards the genus *Brachyurus*, which is little more than *Pithecia* with a shortened tail, Mr. W. A. Forbes has lately shown this to be the case, in an article published in the Zoological Society's *Proceedings*,[2] wherein, after describing the anatomy of *Brachyurus rubicundus*, he has given a map to illustrate the distribution of this and the two allied species of *Brachyurus*. Each of them is limited to a peculiar district of Amazonia, one (*B. melanocephalus*) to the forests of the Rio Negro, a second (*B. calvus*) to those lying between the Putumayo and the Japurá, on the north bank of the Amazons, and the third (*B. rubicundus*) to the district contained between the main stream and the Rio Ica.

In like manner the few particulars which have yet been recorded as to the exact localities of the *Pithecia* seem to tend to similar conclusions. Although we suppose them, in obedience to the Law of Variation, to have originated in common ancestors, they are found in restricted areas cut off from one another by natural boundaries in cases rather widely separated. Why, in these and other cases, the form should have ceased to exist in the intermediate districts, is a subject on which it is at present difficult even to offer a conjecture.

The *Pithecia* are easily divisible into two groups, one embracing the curly-haired species, *P. leucocephala*, *P. monachus*, and their allies, the other the smooth-haired forms, such as *P. hirsuta*, commonly called by the dealers the Jews, and *P. chiropotes*. The White-nosed Saki, of which a figure is herewith given (Fig. 8), belongs to the latter group, and is one of the rarest and least known of all South American monkeys. Only a single example of it was obtained by the late M. Emile Deville, the collector Deville, on the Upper Rio Negro, during his descent of that river in company with de Castelnau's expedition, and is now in the Paris Museum. It was first described by the late M. Isidore Geoffrey St. Hilaire in 1848, and subsequently figured in "Zoologie" of Castelnau's Expedition. The exact locality where it was obtained was unfortunately left unrecorded.

FIG. 8.—The White-nosed Saki.

The example of this monkey living in the Zoological Society's collection, was purchased of a dealer in 1870, and died in the last. It is uniformly, but rather thinly, covered with black hairs, and has the face broadly naked, and of a bright flesh-colour, but shows a few white hairs on the nostrils, which are sufficiently characteristic of the scientific name. The long hairs of the head fall on both sides of the face, and also over the front. The length of the tail is about fifteen inches, of the body about twelve inches. The latter organ, although long, is not prehensile, with elongated hairs, and is not even slightly prehensile. The specimen is apparently of the female sex, apparently not quite adult.

9. *The Mountain Nestor* (*Nestor notabilis*).—Whatever may have formerly been thought to the contrary, there can be now no doubt that birds are continually changing their habits in order to suit themselves to the altered circumstances of their existence. A very remarkable instance of this is that of the common swallow, which, in Europe at least, usually builds its nest in chimneys. Before chimneys were invented it must obviously have affixed its nest to some other kind of structure—probably to the bole of a low tree. But a much more striking and humorous change of habit has of late years taken place in the New Zealand bird, of which we herewith give an illustration (Fig. 9). Parrots, though varying much in the character of their diet, are generally considered to be more or less frugivorous. Fruit and seeds, and in certain cases moss and honey, are, no doubt, their principal food. But since the introduction of the domestic sheep into New Zealand the Mountain Nestor, which was previously content with a modest repast of an entirely vegetable character, has developed a taste for mutton. Numerous instances have now been recorded of this bird attacking not only sick and dying sheep, but, it is alleged, even those that are strong and healthy, though we should rather suppose that this parrot exists anywhere in sufficient numbers to be likely to do the flock-masters any serious

sheepskin on the roof of a hut; and whilst it is engaged in tearing up the bait it is easily approached and snared."

10. *The Gayal* (*Bibos frontalis*).—In the mountainous districts of the oriental region three fine species of wild cattle occur which do not belong strictly to the genus *Bos*—the supposed progenitors of our domestic herds—but to a slightly modified form, *Bibos* of naturalists. One of these—the *Gaur*—inhabits the Ghauts of Central India, and is the well-known "Bison" of Anglo-Indian sportsmen. The Gaur is very intolerant of captivity, and although many attempts have been made to rear young specimens for transmission to Europe, none of them have ever proved successful. A second species of *Bibos*, the Bantang (*B. javanicus*), is found only in the hills of the Malay countries. It is more tractable, and examples of it have occasionally reached Europe alive, though they have not done well in this country.

Of the third *Bibos*, the Gayal (*B. frontalis*), we give a figure taken from a fine pair of these animals now in the Zoological Society's Gardens, which were received from the sister Zoological Society of Calcutta. The Gayal, as Jerdon tells us, in a state of nature inhabits the hilly tracts to the east of the Brahmapootra and at the head of the Valley of Assam, extending into the Mishmi Hills and adjacent ranges. It is caught and kept in captivity by the natives very extensively, and to this fact is no doubt due the comparative ease with which specimens of it are brought to Europe.

The Gayal breeds readily with the different forms of Domestic Ox. Many hybrids between the Zebu and Gayal have been produced in former years in the Zoological Society's Menagerie.

SHIPBUILDING A THOUSAND YEARS AGO

MR. COLIN ARCHER read an interesting paper on this subject at the recent meeting of the Institution of Naval Architects, as also at the York meeting of the British Association.

It is a well-known historical fact that as far back as the early part of the Middle Ages, the inhabitants of Scandinavia were a great seafaring nation: in many of the great battles fought between the chiefs and pretenders of that period—and they were not few—we find several hundreds of large war-ships ranged against each other. It seems to have been quite a common practice for the young chiefs, in order to relieve the monotony of life on shore, or to escape the consequences of some lawless act, to equip one or more ships, manned by their retainers, and to launch forth in quest of adventure, plunder, or "the bubble reputation." And these excursions were not always confined to home waters; they were frequently extended not only to the coast countries of the north of Europe, but also to the shores of the Mediterranean. Iceland was discovered about the middle of the ninth century by Norwegian adventurers, and there are good grounds for believing that an expedition starting from Iceland landed and established a colony in the present New England States nearly 500 years before Columbus lived.

But the descriptions which the old Sagas afford of the vessels in which these expeditions were undertaken, and these battles were fought, are very meagre. It was therefore looked upon as an event of great interest when, on excavating a large grave-mound near the entrance to Christiania Fjord, a ship, evidently from the Viking period, was discovered in a wonderful state of preservation. There is reason to believe that this ship, although comparatively small, does not differ materially in her manner of construction or in shape from the more powerful war-ships, or from those used for long voyages. She is probably a true model of the ships which carried Rollo and his brave followers to the coast of Normandy; and it may therefore be assumed that a brief description of her, as she now appears from a shipbuilder's point of view, may not be without interest.

It was not to be expected that a delicate structure such as this Viking ship could remain for eight or ten centuries buried many yards under ground without sustaining some damage, or that she should perfectly retain her original form. It is rather a matter of surprise that the damage is so small as it is. Thanks to careful handling and a judicious arrangement of supports, there is reason to believe that, apart from local strains and contortions of form, the hull as it now stands represents very closely the ship as she appeared when put into the ground. Mr. Archer has taken off her lines with as much accuracy as circumstances would permit, and, referring to these lines, he explains the chief peculiarities of the construction.

The principal dimensions are:—

	Feet.	Inches.
Length between the rabbets at gunwale	77	11
Breadth, extreme	16	7
Depth from top of keel to gunwale amidships	5	9

The vessel is clinker built, and the material all oak. There are sixteen strakes of outside planking, the ordinary thickness 1 inch, average breadth amidships 9 inches, including 1 inch land. The lengths vary from 8 to 24 feet. The scantling is not, however, uniform throughout; thus the tenth plank from the keel is about 8 inches broad and 1¾ inches thick, and forms a shelf for the beam-ends. The fourteenth plank from the keel, or third from the top, is about 10 inches broad and 1¼ inch thick. This plank, which we may call the "main wale," is perforated with holes for the oars, sixteen on each side, about 4 inches diameter, and provided with a slit at the after and upper edge to allow the blades of the oars to be passed through from inboard. The two upper strakes are the thinnest of all, being scarcely more than ⅝ inch. The gunwale, 3 inches by 4½ inches, is placed in the usual manner inside the top strake. The boards are throughout united to each other by iron rivets about the thickness of an ordinary 3 inch spike, spaced from 6 to 8 inches, with large flat heads 1 inch diameter. The riveting plates are square or nearly so, ⅝ inch. The nails are driven from the outside, except near the ends, where riveting inside would have been difficult from the sharpness of the vessel. The nails are here driven from the inside and riveted outside. The garboard strake is fastened to the keel with rivets of the same kind as those used for joining the strakes with each other.

The keel is of a peculiar shape; it is about 14 inches deep, of which 11 inches are below the rabbet, 4½ inches thick at the lower edge, and only 3 inches at the rabbet. The top of the keel is 7 inches broad, thus affording a large surface for the garboard strake, besides combining strength with lightness. Possibly also the increased thickness of the lower edge may have been adopted to improve weatherliness under sail. It is difficult to say where the keel ends and the stem and sternpost begin, as these run into each other with a very gentle sweep; but the piece of wood which may be called the keel proper is 57 feet long; to it are joined a short forefoot and heel piece by short vertical scarfs secured by double rows of rivets. These pieces again are fitted in a similar manner to the stem and stern-post. The posts are sided 3 inches, chamfered to 2 inches outside edge. They are 15½ inches broad outside the rabbet just above the scarf, decreasing in breadth upwards.

The framing of the bottom consists of grown floors extended in one piece from shelf to shelf. The average spacing in the body of the vessel is about 3 feet 3 inches from centre to centre, greater at the ends: there are nineteen frames in all. The floors are neatly finished, of a shape which combines strength with lightness and elasticity. The lower surface has a flat projection in which are holes for receiving the fastenings for the plank. The way these fastenings are managed is very peculiar. The

Digitized by Google

planks are evidently worked down from stout slabs, and in doing so a ledge an inch high has been left on the inner surface running along the middle of the plank. The floors are not fayed down on the boards; they have only two points of contact with them, the upper edges and the ledge above mentioned, in which are two holes bored transversely, one on each side of the timber. Through these holes and corresponding holes in a fore and aft direction through the timbers are passed ties made of the tough roots of trees. These ties are very slight, scarcely ¼ inch diameter; they are crossed over the ledge on the board, only passing once through each hole. The ledge has been removed in the spaces between the timbers, so that the remaining parts under the timbers look like cleats fastened to the plank. With the exception of a nail driven through the "shelf" and riveted on the extreme end of the floors, these ties seem to be the only fastenings used at this part of the vessel. The floors are only about 4 inches diameter, a foot from the garboards, and taper, siding as well as moulding, down to 3 inches or even less at the shelf. They are not fastened to the keel.

As already stated, the beams, which are sided 7 inches, moulded 4 inches, rest on what Mr. Archer has called the "shelves," which however only differ from the ordinary planking by being ¾ inch thicker, and of greater lengths, the longest piece being about 48 feet. The beam-ends also rest on the ends of the floor timbers. They are secured by knees extending down the ship's side from the upper edge of the "main wale" with an arm on the beam. These knees are fitted close to the planking at the side, and fastened with oak trenails. Being a little narrower than the beams, a ledge is formed on each side for the bottom boards or flooring, which is made to fit into these ledges from beam to beam, thus forming a continuous platform. A strip of wood is nailed on top of the beams in continuation of the knees where these are too short to welt from opposite sides. The beams are supported amidships by pillars resting on the throats of the floors. The top sides, consisting of the two thin boards already mentioned, are connected with the body of the ship by independent timbers intervening between the knees, and extending from the under side of the gunwale some distance down the side, but not so far as the platform. There are no timbers in the upper part of the vessel, overlapping or making a shift with the floors.[1]

It will be seen that by this system of construction the upper portion of the ship is altogether unconnected with the bottom part, so far as framing is concerned, an arrangement which would scarcely be safe where much ballast or a heavy cargo is carried on the ship's bottom. No doubt heavy weights when carried were placed above the platform, in which case there would not be the same tendency for the two sections to part company.

Perhaps the most singular part of this singular ship is the arrangement for stepping and supporting the mast. The step is a solid log of oak 11 feet long and 19 inches broad by 14 inches deep at the middle, tapering to the ends. It is counter-sunk over the throats of the floors, to which it is fastened by means of small knees on either side. From this trunk a branch grows out vertically in front of the mast and quite close to it. This branch, which is nearly 12 inches thick, is fastened to what Mr. Archer has called the "fish."

The fish is a ponderous piece of oak lying along the middle line of the vessel, on top of the beams, and extending over five spaces. It is 16 feet long, 38 inches broad, and 14 inches deep at the middle. This block is modelled so as to represent the tails of two fishes or whales resting on a flat slab or sole piece about 4 inches thick. The slab is counter-sunk over the beams and well secured to them by knees. A large slice is taken off the back of the fish, the upper surface thus forming two planes inclining to either end. The extreme ends of the tails are only about 3 inches thick above the slab. A slot 5 feet 9 inches long and 12½ inches wide (the diameter of the mast) is cut in the fish from a point a little in front of the middle towards the stern. The mast is stepped through the forward end of this slot, and when erect kept in its place by a heavy slab fitted into the slot. In the end view this slab is shown with the after end raised level with the forward end. By removing the slab and slacking off the fore-stay the mast would be free to fall aft in the slot, and could thus easily be lowered. In order that the beam nearest the mast should not interfere with this manœuvre there is a depression in it which enables the mast to fall back the whole length of the slot.[1] There is a stanchion about 8 feet high, with a cross-beam at top in which are semicircular depressions for the spars to rest in when not in use. There have been three such stanchions.

The mast, which is 12½ inches diameter, has been cut about 10 feet from the foot. The extreme top of one of the spars found in the ship, corresponding in size to the part which remains, has rotted away; but if this spar, as seems probable, is the upper portion of the mast, the whole length may have been 40 feet. There is another spar which looks as if it might have been the yard. It is broken off near the middle, but Mr. Archer estimates its full length at 35 feet, diameter at slings 8½ inches, at arms 3½ inches. Abreast of the forward end of the fish, strong pieces of wood, one on either side, each with two circular sockets, are fitted down between the timbers just above the platform. Possibly one of these sockets may have served as a step for a squaresail boom. The other may have received a pair of shears to give elevation to the fore stay when raising or lowering the mast.

With regard to the rudder, a conical piece of wood sufficiently long to keep the rudder clear of the ship's side is fitted with its base to the outside planking; through a hole bored through the centre of the cone, and a corresponding hole in the rudder, a stout rope is rove, provided with a knot at the outer end and made fast inboard. This rope acts as a pivot, allowing the rudder to be twisted by means of the tiller fitted athwartships. An iron staple near the lower extremity of the rudder, and a small ring bolt at the upper end may have been fitted with guys leading aft to steady the rudder and keep it immersed when the ship was under way. The rudder-head or stem is round, 6 inches diameter. At the pivot it is 7 inches thick, thence decreasing in thickness downwards. The breadth is 15 inches at pivot, increasing to 22 inches at foot. Both edges are bevelled off, particularly the front one, which is reduced nearly to a feather edge. The rudder is all of one piece of wood.

The extreme ends of the vessel are unfortunately gone, so that it is not easy to see how she has been finished off here. The lower planking takes a very decided turn upwards as it approaches the ends, running in fact almost parallel with the posts. If therefore all the wood ends have joined the posts, these must have been very high. It seems not improbable that part of the planking has been received into a rabbet in the gunwale, or in a breast-hook connecting the gunwale with the stem or sternpost. This however is merely a conjecture.

If the old ship can be looked upon as a fair sample of the ships of her time, it is evident that shipbuilding a thousand years ago was something very different from what we now understand by that term. What strikes one most forcibly on seeing this vessel as she now stands is the extreme lightness of her scantling and the total absence of anything in the shape of lining, longitudinal stringers, or similar contrivances for giving what we

[1] This mode of binding the two sides together by means of beams halfway between gunwale and keel is still practised in the west and north of Norway. Even small skiffs are tied together in this way, loose thwarts being placed over the beams, only resting in a notch cut in the knees which secure the beams, while the floor-timbers merely butt up against the beams.

[1] In the Scandinavian languages the technical term for the framing which now takes the place of this colossal structure in our modern ships—the mast partners—is still *Fisken*, the fish.

Digitized by Google

should consider the strength and rigidity necessary in a sea-going vessel. It would however be unfair to compare her with a ship of modern build of the same size. Even the designation "ship," as applied to her, is apt to convey a false idea. She is in fact a very large sailing rowing-boat.

These ancient vessels may be considered as consisting of two distinct sections, each having its special use and function. The portion above the beams is the hold proper, the useful space. Here the crew had their abode, and here was carried probably all that the vessel had to carry, and this portion is comparatively strong. The material is no doubt here also of small dimensions, but what there is has been judiciously distributed, is of good quality, and has been well put together. It should also be remembered that the weight carried was small in quantity as compared to the carrying capacity, and consisted principally of live cargo, and this kind of loading is much less trying to a vessel in a seaway than a similar loading of dead weight would be. The lower portion of the ship, on the other hand, had a different kind of duty to perform. It had to supply the "form" necessary for small resistance and rapid locomotion, and to float the upper section: keeping this in mind it will be found that her construction gives evidence of a great deal of practical skill and ingenuity. Every part of the vessel is sufficiently strong for the duty expected of her, while at the same time economy of weight of material has been studied throughout. It will be seen that the weight of the superstructure is taken entirely by the floor timbers, the ends of the beams resting on them, while the beams are supported amidships by the props stepped in the throats of the floors. There would therefore be very little stress on the ties of the bottom planking, which latter, there being no counteracting pressure on it from the inside, would always tend to cling to the timbers by the pressure of the water outside. The only weight of any moment which would tend to separate the two sections of the boat is the mast, and this tendency is met by the "branch" of the step being secured to the "fish." Still there can be no doubt that this boat must have possessed a pliancy and mobility in a heavy sea which we should look upon as ominous in a modern sea-going craft. Her real safety consisted in a tough and elastic outer skin, which would be the more invulnerable from not being made unduly rigid at any point. Thus her apparent weakness was her real strength. Mr. Archer has not been able to discover anything deserving the name of a bolt in the whole structure. The stoutest iron fastenings are the rivets in the scarfs of the keel and the nails securing the inside knees, and they are no stronger than ordinary 4-inch spikes.

It seems probable that such a boat would be capable of great speed, even under oars alone; with a fair wind she must have been very fast. Mr. Archer has assumed a low water-line, and finds that at this trim her displacement is 994 cubic feet, or 28·4 tons; area of immersed midships section 24 square feet; extreme length on load-line, 73 feet 3 inches; and draft of water 3 feet 8 inches. Allowing 10 tons for her complement of 100 men with their accoutrements, leaves 184 tons for the vessel, with inventory, stores, and equipment, and this allowance is probably ample. The areas of cross-sections are obtained by multiplying the ordinates of the curve by 4 feet.

LEARNED SOCIETIES IN JAPAN

IT is now a little more than ten years since Japanese students began to flock in large numbers to the various schools of Europe and America, after the great revolution which completely altered the political, and in many respects the social, organisation of the country. Many of these young men travelled and studied at their own expense; but the majority was selected by the principal Government departments, and the expenses paid from the Imperial funds. For six or seven years the numbers continued without diminution; but soon after the commencement of the Satsuma rebellion in 1877, when the heavy strain on the Imperial Exchequer caused by the suppression of that outbreak began to be felt, it was decided to economise the public expenditure in various ways, and amongst others by reducing the number of those studying abroad at Government expense. The result of this measure, which was forced on the Ministers by unfortunate circumstances, was that many Japanese young men who spent some years in the principal educational establishments of western countries returned to their own land with a sound training in their respective branches of study. It would not be desirable, even if it were possible, to enter here into the question how far they have fulfilled the hopes with which they were first sent abroad. Many of them have had brilliant careers amongst their foreign fellow-students, and, on the whole, we believe they have done as much as any body of English students, similarly placed, could have in the same time; but it is another question whether they are fitted to assume the places held by the foreign professors and instructors in the various educational institutions of the country. It was to this that the Government looked when they were first despatched to Europe; but, from a combination of causes, it is doubtful whether the laudable and patriotic desire to be, as far as possible, independent of extraneous assistance, has been so completely fulfilled as was originally anticipated.

One result has undoubtedly attended this great influx of men trained after western methods, namely, the thirst for scientific knowledge of all kinds amongst the educated classes in Japan. It is hardly an exaggeration to say that Japanese literature, as an indigenous product, is for the present almost in abeyance. If we examine the monthly catalogue of books for which licence to print is granted by the Censorate in the Home Department in Tokio, it will be seen that a very large proportion is composed of translations or adaptations of European or American scientific or literary works. Besides translations made at the expense of the public departments, we find private individuals throughout the country utilising their knowledge of a western language by translating from it, for the benefit of their countrymen. Thus, not to mention innumerable "Lives" of Wellington and Napoleon, or translations of "Gulliver's Travels," "Robinson Crusoe," and other books of this description, the works of Huxley, Carpenter, Peschel, Darwin, Tyndall, Quatrefages, Lyell, Buckle, Mill, &c., &c., have all been translated or adapted with more or less success for the Japanese reader. Societies, on the European model, have also been formed, and it is with these that we are chiefly concerned at present.

Centuries before the Royal Society of Great Britain was founded men interested in the pursuit of some study or accomplishment in Japan had formed themselves into societies, some of which still exist. Collectors of antiquities, of coins, of the handwriting of celebrated men of ancient times, met at stated intervals to exhibit and discuss the authenticity of their treasures; *go*-players had their own organisation, with branches in all the chief towns throughout the country, and headquarters in the capital, where the leaders met for trials of skill. These latter even had a kind of magazine in which problems for solution were set, and the moves in remarkable games recorded. These meetings generally took place in the evening, at some well-known house of entertainment. There was no formal reading of papers, with discussion afterwards; a member exhibited some new object, related briefly all he knew about it, and asked for any further information that could be afforded by those present. Frequently also these meetings were used for effecting

Digitized by Google

sales or exchanges amongst the members. Some of these old societies still flourish in undiminished vigour, unaffected by the changes which have passed over the country and altered all around them. Amongst these are the *Kō-butsu-sha*, or Antiquarian Society, the Numismatic Society, the Association of *Go*-players, and many of the old assemblies for literary and poetical contests. But the new era has been productive of societies of a more scientific kind, based on the models of learned associations in Europe and America. Founded by students fresh from abroad, they have received the support of men of wealth and eminence, and, judging from the experience of the past few years, they seem in a fair way to attain permanent success.

The most important of these associations is the Geographical Society of Tokio, which now numbers about 200 members. The subscriptions, which are very small, are largely increased by donations from the wealthy members. It is under the patronage of several of the imperial princes, and among its members are the chief personages of the Empire. The *Transactions* are neatly printed in small pamphlets of about 100 pages each, and contain much matter which would be valuable even to European geographers. With the exception of China, Japan is the only foreign country having intercourse with Corea. Our information respecting this peninsular kingdom is limited to the imperfect accounts of the Jesuit priests; but the Japanese Geographical Society has already had several interesting and important papers on the subject from its members. The difficulties of the language seriously restrict the circulation of these and other papers, but we believe the Committee are contemplating the publication of translations of their *Transactions*.

During his too brief stay in Japan as occupant of the Chair of Zoology in the University of Tokio, Prof. Morse of Salem, Massachusetts, was instrumental in establishing a Biological Society which attracted much attention. It is now being conducted successfully by Prof. Yatabe, a Japanese gentleman educated in the United States.

Another association, which is, we believe, unique among the societies of the world, is the *Kojunsha*, or Society for the Circulation of Knowledge. Its head-quarters are at Tokio, but there are branches in every town of importance in the Empire. It possesses a secretary and staff of clerks, and a member desiring to obtain information on any subject applies to the secretary. The latter has on his books the names of all the members likely to be able to satisfy the applicant, and immediately transmits the question to them. The answers are forwarded in due course to the inquirer, and should the subject be deemed by the Committee of sufficient general importance, the whole is printed in the weekly *Journal* of the Society. The pains which are taken to obtain satisfactory replies to queries are, we can vouch from personal experience, almost incredible. It is not surprising to learn that this Society has nearly 3000 members scattered throughout the Empire, and even in Europe and America. As a device for bringing together the active and inquiring minds of the country, it is almost unequalled. The subscription, which includes the use of reading-rooms and the numbers of the *Journal*, is about half-a-crown per month.

The Numismatic Society, to which we have already referred, is also very active. It publishes a periodical describing new and strange coins that have been exhibited at its meetings, and supplies other information interesting to collectors.

We need not refer here to the English and German Asiatic Societies founded in Yokohama and Tokio. They are under the control of foreign residents, their papers are in a foreign tongue, and, although their work has been most valuable, they are outside the scope of the present article. Nor need we give more than a passing reference to the innumerable political societies which have sprung up like mushrooms in all parts of the country during the past few years. If the objects of the promoters of these organisations were less palpably selfish, and more in accordance with their high-sounding titles, they would be very important instruments in the education of the people.

But we cannot pass over the latest scientific association of Japan. The Seismological Society, as its name indicates, is founded for the purpose of investigating volcanic and earthquake phenomena of all kinds. Japan is particularly well situated for this object. There are numerous active and extinct volcanoes throughout the island. Mild earthquakes are of very frequent occurrence, so that the student has not, on the one hand, to wait months for his subject, as in most parts of Europe, or, on the other, to run for his life when it does come, as in South America. This society was founded chiefly through the energy of its vice-president, Mr. Milne, professor of geology in the Engineering College at Tokio, who has long made seismic phenomena a special study. A Japanese, Mr. Hattori, himself a student of the subject, is President of the Association, which numbers many foreigners amongst its members. The Central Government have throughout taken a warm interest in the success of the Society, and have, we believe, placed the telegraph lines at its disposal, and ordered the local officials all over the country to report all occurrences connected with earthquakes and volcanic eruptions in their districts. A few months since, under the auspices of the Society, an exhibition of seismological instruments of various kinds—one of them as ancient as A.D. 126—took place in Tokio. The number of visitors in one day to the rooms was over 2000, a fact which attests the interest taken in this study by the Japanese. The *Transactions* of the Society are published in English in the *Japan Gazette* newspaper of Yokohama.

The army, navy, and other professions have their own societies and newspapers, very much as in England. One of the most curious of these class or trade journals is the dancing-girls' paper, containing portraits and biographies of the chief *danseuses*. We have not advanced so far yet in England as to have an organ-grinders' gazette!

On the whole it must be pronounced that the outlook for the propagation of scientific knowledge in Japan is hopeful; and there seems no reason to fear that science will suffer greatly after the approaching and inevitable departure of all foreign instructors in the country. They will leave behind men who, although possibly not such efficient teachers, are animated by all the thirst for knowledge that animates the bulk of scientific men in western lands.

NOTES

Dr. C. W. Siemens has received from the French Government a formal document nominating him "Officier de l'Instruction Publique," the nomination being accompanied by the insignia of the order, which corresponds, we believe, to the Prussian order "Pour le Mérite."

It is proposed to open an International Electrical Exhibition at the Crystal Palace in December.

The anatomical department of Edinburgh University has lost a valuable servant in the death, at the age of seventy, of Mr. A. B. Stirling, the assistant conservator of the Anatomical Museum. He was born in 1811 at Milngavie, Stirlingshire, where his father was a shoemaker. Stirling early evinced a decided liking for natural history studies; he was a born naturalist. His love of natural history brought him into contact with the late Prof. John Reid and Dr. Adamson of St. Andrews, who employed him to

Digitized by Google

arrange the University Museum there. In 1856 he was introduced to the late Prof. Goodsir, who recognised his aptitude for anatomical work, and saw in him one who would be a congenial helper in the work which he had in view; and Mr. Goodsir appointed him assistant conservator of the Edinburgh Anatomical Museum—a museum which he has enriched with hundreds of anatomical preparations (normal and morbid), and also many comparative anatomy specimens, which are all characterised by great taste in the way in which they are mounted. He soon acquired an extensive knowledge of anatomy, human and comparative; he had so remarkable a mechanical turn, and so inventive a mind, that he devised many new methods for preserving the human body for dissection, for mounting anatomical preparations, for cutting microscopic sections, and for mounting the same. He was an accomplished microscopist and a keen fisher, and this led him to take a great interest in fish, especially the Salmonidæ; and, when the "fungous disease" broke out amongst the salmon in the Tweed and other rivers, he investigated this matter, and communicated his results to the Royal Society of Edinburgh—results which are said to contain by far the best description yet given of the pathological conditions of this remarkable disease. Not only did Mr. Stirling encourage and aid others, but, in turn, he was the esteemed and highly valued friend of the late Prof. Goodsir and of Prof. Turner, both of whom gave him every facility for carrying on his investigations.

THE Royal Commission on Technical Instruction visited Saltaire and Keighley on Tuesday, and were present at the annual meeting of the School of Science and Art in the Keighley Mechanics' Institute. Mr. Slagg, M.P., speaking of the objects of the Commission, said that their great aim would be to develop a plan by which their system of primary education should be linked to a higher system, comprising a higher training and leading up to the highest scholastic education the country could afford. For his own part he did not see anything at the present moment in foreign competition to appal them in the slightest degree, and substantially he believed that they held their ground very well indeed. Mr. Samuelson, M.P., said that it was impossible that they as a nation could continue to hold the superior rank which they had taken among manufacturing countries if they did not cultivate the industrial intelligence of their population, and it was on that account that he thought the Commission would result in great good.

A REMARKABLE phenomenon occurred in New England on September 6, almost exactly similar to one that occurred in the same region on May 19, 1780. The *Springfield Daily Republican* describes it as follows:—In this city the day began with a slow gathering of fog from all the watercourses in the early hours, the thin clouds that covered the sky at midnight seemed to crowd together and descend upon the earth, and by sunrise the atmosphere was dense with vapour, which limited vision to very short distances, and made those distances illusory; and as the sun rose invisibly behind, the vapours became a thick, brassy canopy, through which a strange yellow light pervaded the air and produced the most peculiar effects on the surface of the earth. This colour and darkness lasted until about three o'clock in the afternoon, once in a while lightening, and then again deepening, so that during a large part of the time nothing could be done conveniently indoors without artificial light. The unusual complexion of the air wearied and pained the eyes. The grass assumed a singular bluish brightness, as if every blade were tipped with light. Yellow blossoms turned pale and gray; a row of sunflowers looked ghastly; orange nasturtiums lightened; pink roses flamed; lilac-hued phlox grew pink; and blue flowers were transformed into red. Luxuriant morning-glories that have been blossoming in deep blue during the season now were dressed in splendid magenta; rich blue clematis donned an equally rich maroon; fringed gentians were crimson in the fields. There was a singular luminousness on every fence and roof-ridge, and the trees seemed to be ready to fly into fire. The light was mysteriously devoid of refraction. One sitting with his back to a window could not read the newspaper if his shadow fell upon it—he was obliged to turn the paper aside to the light. Gas was lighted all over the city, and it burned with a sparkling pallor, like the electric light. The electric lights themselves burned blue, and were perfectly useless, giving a more unearthly look to everything around. The darkness was not at all like that of night, nor were animals affected by it to any remarkable extent. The birds kept still, it is true, the pigeons roosting on ridge-poles instead of flying about, but generally the chickens were abroad. A singular uncertainty of distance prevailed, and commonly the distances seemed shorter than in reality. When in the afternoon the sun began to be visible through the strange mists, it was like a pink ball amidst yellow cushions—just the colour of one of those mysterious balls of rouge which we see in the drug-stores, and which no woman ever buys. It was not till between five and six o'clock that the sun had sufficiently dissipated the mists to resume its usual clear gold, and the earth returned to its everyday aspect; the grass resigning its unnatural brilliancy and the purple daisies no longer fainting into pink. The temperature throughout the day was very close and oppressive, and the physical effect was one of heaviness and depression. What was observed here was the experience of all New England, so far as heard from, of Albany and New York city, and also in Central and Northern New York. In reference to this phenomenon the New York *Nation* suggests that it may be worth the while of weather-observers to note the approximate coincidence between the interval separating the two dark *days in* New England (May 19, 1780, and September 6, 1881) and nine times the sun-spot cycle of eleven years.

THE ceremony of cutting the first sod of the Giant's Causeway and Portrush Tramway was performed the other day at Portrush, in presence of the directors and a large company of the local gentry and visitors at Portrush. Interest was attached to the ceremonial owing to the fact that it is intended to work the tramway by electricity, the company thus being the first to introduce into the United Kingdom electricity as a motive power for tramway and railway propulsion. The chairman of the company, Dr. Traill, said that not many years would elapse before this dynamo-electric power would be supplied, not alone to tramways suitably situated for it, as this one undoubtedly was, but also to railways. To shareholders in a company such as this they could easily see what an important thing such a revolution in locomotive power would represent. The working expenses for haulage on a tramway such as theirs with horses would be about 11*d.* per mile, and by steam power about 7*d.* per mile, but there was every reason to suppose that the working expenses of their motive power need not reach 1*d.* a mile.

SOME time ago we gave an account of the nature and uses of celluloid. Among other things it may be used for preserving typographical *clichés* and stereotypes. The process employed for this purpose, we learn from *La Nature*, consists in taking an impression of the engraved block by means of a special cement which receives the impression and rapidly hardens. After about twenty minutes the cement can support a pressure of 250 kilogrammes. The presses used to take the first impression ought to be heated; and the celluloid in sheet is then used to take the counter-impression from which to print. Celluloid shows the typographical reproduction of specimens of lace in a marvellous fashion, by the actual impression of the lace itself. *La Nature* gives an illustration of a piece of lace engraved in this manner, and the reproduction of the pattern is perfect.

A TELEGRAM from Constantinople of September 30 states that an earthquake had occurred at Changeri, in Anatolia, which

Digitized by Google

caused the death of eleven persons and great injury to the Grand Mosque and numerous dwelling-houses. The amount of damage done in the neighbouring villages is not known.

A GEOGRAPHY of the almost unknown kingdom of Corea has been compiled by a member of the suite of the Japanese envoy to that country. Several valuable papers containing accounts of travels in Corea have been read before the Geographical Society of Tokio, and have appeared in its *Transactions*. As they are written in Japanese they are unfortunately all but inaccessible to European geographers.

THE Prefect of the Seine has established a course of six lectures for the teaching of micrography. An examination has been instituted for inspectors intrusted with the care of detecting trichinæ in the substance of pork and ham of American or German origin.

A CURIOUS experiment will be tried this week at La Villette gasworks, Paris. Two balloons of equal size will be sent up at the same time; one of them will carry an experienced sculler, who is confident that he will produce some effect with a long oar of his invention.

UNDER the title of "School Physical and Descriptive Geography" Mr. Stanford has issued a smaller and cheaper edition of the late Keith Johnston's "Physical, Historical, Political, and Descriptive Geography," reviewed in these pages at the time of its appearance. In the school edition the historical sketch and the elaborately-printed maps have been omitted, while all the strictly geographical information has been retained. In this form it ought to find wide acceptance among all teachers who aim at making geography both interesting and thorough. No better text-book could be recommended.

THE subject of the address by Shadworth H. Hodgson, LL.D., before the Aristotelian Society on Monday evening will be "The Practical Bearing of Speculative Philosophy."

WE have received from Rothschild of Paris an interesting little volume on Pisciculture in France. It consists of two parts—Pisciculture, Fluvial and Maritime, by Jules Pizzetta; and Oyster-Culture, by M. De Bon.

IN its summary of colonial intelligence the *Colonies and India* mentions the discovery of a valuable coal-seam near Victoria, Huon, Tasmania, which has been traced on the surface for about twenty yards, and increased in width from three to four feet, when it was lost in a hill. The coal has been tried and found to be of good quality.

A VALUABLE archæological discovery, which may be said to equal that of the celebrated Kertch antiquities at the Hermitage of St. Petersburg, has recently been made near the Cossack village of Sewersk in the Sakuban district, in one of the *kurdans*, *i.e.* the old tombs, in the steppes of Southern Russia. A number of objects were found, but special attention was drawn to two glass vessels, unfortunately broken, but the pieces of which still give evidence of their remarkable ornamentation. They are profusely covered with gold, the hoops containing large rubies and bearing golden chains, by which heart-shaped pearls are suspended. Another object of cylindrical shape, evidently a cup-holder, consists of pure gold, and shows two griffins in bas-relief. Another important object is a gold plate six inches in diameter, with a fine bas-relief representing a whole episode. M. Felizin, an eminent Russian archæologist, is of opinion that the tomb in question must have been that of an important personage of the Bosphorean kingdom, and that its origin dates back as far as the period of King Perisad II., who began to reign in the year 284 B.C. A gold coin which was found confirms this view.

AN important discovery of very good rock-salt, affording a sheet seventy-five feet thick, was made some days ago in the district of Bakmut, in the Russian government of Ekaterinoslav, at a depth of 430 feet. The discovery was made according to the indications of the geologist, Prof. Erofeeff.

THE anniversary address of the Hon. Prof. Smith, president of the Royal Society of New South Wales, contains an interesting sketch of the history of the Society, both under its old name of Philosophical Society as well as under its present designation.

MESSRS. BLACKWOOD AND SONS have issued a twelfth edition of the "Elements of Agricultural Chemistry and Geology," by the late Prof. J. F. W. Johnston and Dr. C. A. Cameron.

IN the report sent us of the meeting of the Natural History Society of the Friends' School at York, and printed among our Notes a fortnight ago, the Rev. T. A. Preston is referred to as science master at Marlborough College. Of course this is a mistake; Mr. G. F. Rodwell has long held and still holds the post referred to.

THE additions to the Zoological Society's Gardens during the past week include a Tennant's Squirrel (*Sciurus tennanti*) from Ceylon, presented by Mrs. S. A. Cottrell; a Common Marmoset (*Hapale jacchus*) from South-East Brazil, presented by Mr. J. N. Palmer; a Chacma Baboon (*Cynocephalus porcarius*) from Sout Africa, presented by Mr. W. H. L. Long; a Leucoryx Antelope (*Oryx leucoryx*) from North Africa, presented by Mr. John M. Cook; two Leopards (*Felis pardus*) from Ceylon, presented by Mr. Eustace L. Burnside; a Green Lizard (*Lacerta viridis*) from Jersey, presented by Mr. James Thorn; a Tarantula Spider (*Mygale*, sp. inc.) from California, presented by Mrs. John Leechman; five Robben Island Snakes (*Coronella phocarum*) from South Africa, presented by Rev. G. H. R. Fisk, C.M.Z.S.; two Greater White-crested Cockatoos (*Cacatua cristata*) from Moluccas; two Common Cormorants (*Phalacrocorax carbo*), British, deposited; two Blossom-headed Parrakeets (*Palæornis cyanocephalus*) from India, a Nose-horned Viper (*Vipera nasicornis*), a Crocodile (*Crocodilus*, sp. inc.) from West Africa, purchased.

OUR ASTRONOMICAL COLUMN

COMET V., 1863.—With reference to a remark in this column at p. 111 of the present volume of NATURE, suggesting that a further and more minute discussion of the elements of this comet might be desirable, Prof. Valentiner, director of the Observatory at Carlsruhe, has been good enough to draw our attention to a memoir by himself upon the subject which we had overlooked; it is entitled "Determinatio orbitæ Cometæ V. anni 1863," and was published at Berlin in 1869. The observations, about 130 in number, extend from 1863, December 28, to 1864, March 1, and Prof. Valentiner forms nine normal positions upon them. The perturbations of the earth and Jupiter are taken into account (the comet having approached the former at the end of January within about 0·18) and the following parabolic elements result:—

Perihelion Passage, 1863, Dec. 27·79992 M.T. at Berlin.

Longitude of perihelion	60 24 26·4	M. Eq.
,, ascending node ...	304 43 23·2	1864·0
Inclination	64 28 44·2	
Log. perihelion distance	9·8873326	

Motion—direct.

The agreement with the observations is so close as to prove that the orbit did not sensibly differ from a parabola; the conjectured identity with the comet of 1810 is therefore shown to be inadmissible, notwithstanding the striking similarity of the elements, as will appear from the comparison at p. 111.

THE NEW COMET.—Mr. S. C. Chandler, jun., has telegraphed to Lord Crawford's Observatory approximate elements of the comet discovered by Mr. Barnard last month, from which it appears that the orbit does not resemble that of any which has

Digitized by Google

been previously computed. Expressed in the form usual in our catalogues the elements are :—Perihelion passage, September 15·61 G.M.T. ; longitude of perihelion, 250° 4′ ; longitude of ascending node, 260° 43′ ; inclination, 72° 33′ ; log. perihelion distance, 9·70535 ; motion, retrograde. The intensity of light is diminishing.

MINIMA OF ALGOL.—The under-mentioned Greenwich times of minima of this variable are from Prof. Winnecke's ephemeris, in the computation of which correction depending upon recent observations has been applied :—

	h.	m.		h.	m.		h.	m.
Oct. 9 ..	15	52	Nov. 1 ...	14	23	Dec. 11 ...	17	48
12 ...	12	41	4 ...	11	12	14 ...	14	37
15 ...	9	30	7 ...	8	1	17 ...	11	26
18 ..	6	19	21 ...	16	5	20 ...	8	14
			24 ...	12	54	23 ...	5	3
			27 ...	9	43			
			30 ...	6	32			

There would appear to have been perturbations in the period during the last few years which are not reached even by Prof. Schönfeld's formula involving two inequalities, which would make the above times about thirty-five minutes later.

A PROBABLY VARIABLE STAR.—Prof. Pickering notifies his observation of a red star, with banded spectrum, the place of which on September 14 was in R.A. 16h. 31m. 32s. ; Decl. + 72° 32′. On September 17 its magnitude was 8·6. It is not found in the "Durchmusterung," nor in Federenko, Schwerd, or other circumpolar catalogue. Its variability is therefore suggested.

CERASKI'S VARIABLE, U CEPHEI.—Mr. Knott informs us that he obtained a good observation of the minimum of Ceraski's variable of short period on the night of October 2 ; time of min. 11h. 47m. G.M.T., mag. 9·2. Prof. Schmidt's ephemeris in *Astron. Nach.*, No. 2382, has 11h. 37·5m. The star did not fall quite so low, as in the minima which Mr. Knott observed in March, April, and May last.

[ERRATUM.—In last week's "Astronomical Column" (p. 520), *for* "add *p*" *read* "add P."]

CHEMICAL NOTES

MM. SCHUTZENBERGER AND COLSON describe (*Compt. rend.*) several new compounds of silicon. When crystalline silicon is strongly heated in a current of carbon dioxide the compound $(SiCO)_x$ is produced. When nitrogen is passed over a hot mixture of silicon and carbon $(Si_2C_2N)_x$ is formed. The authors regard these compounds as the oxide and nitride respectively of the radicle *carbo-silicon* $(Si_2C_2)_x$. The nitride of silicon $(Si_2N_3)_x$ is also described : it is obtained by the direct union of nitrogen and silicon.

IT is well known that certain metallic chlorides, *e.g.* sodium chloride, are precipitated from aqueous solution by hydrochloric acid ; attention has been drawn in these Notes to recent work of Ditté and others on this subject. M. Sabatier describes several hydrates of ferrous and ferric chloride (*Compt. rend.*) produced by this general reaction.

MANY years ago Graham drew attention to the change in properties produced in certain oxides by the action of heat, *e.g.* ferric oxide is soluble in hydrochloric acid, but when strongly heated it becomes almost insoluble. This "department of corpuscular philosophy"—to use Graham's phrase—has not been much studied. The experiments detailed in *Archiv Néerland* by M. van Bemmelen form an interesting contribution bearing on this subject. It is shown that the amount of water of hydration taken up by the oxides of tin, silicon, and manganese at the moment of the formation and precipitation of the hydrates of these oxides from aqueous solutions, is dependent on the molecular state, *i.e.* on the as yet unknown conditions of molecular equilibrium, of the solid hydrates. The molecular state being the same, the amount of water of hydration rises with temperature and humidity of the surrounding air ; to each temperature and degree of humidity corresponds a certain equilibrium of oxide and water ; the relations between the weights of the oxide and water are generally too complex for expression by a simple formula. From an examination of the phenomena attending the action of the amorphous hydrated di-oxides of the above-named elements on acids, alkalis, and salts, M. van Bemmelen concludes that weak double compounds are produced, but that these are very easily dissociated ; the amount of dissociation varying with the chemical nature and the mass of the reacting substances, and with the temperature. In most cases stable compounds are produced simultaneously with these series of unstable and largely-dissociated compounds. The formation and dissociation of such unstable compounds depend also on the conditions of molecular stability of the hydrated oxides themselves. By arranging these conditions so as to insure considerable molecular stability—*e.g.* by heating the hydrates—the power of forming the unstable compounds is much diminished. That a force of the same nature as chemical affinity is concerned in the formation of some of these weak compounds is shown by the decomposing action exerted by hydrated MnO_2 on the stable compounds K_2SO_4, KCl, and KNO_3, compounds which do not show signs of dissociation in aqueous solution. M. van Bemmelen would thus extend the sphere of chemical phenomena, and would see no sharp division line between the actions of the so-called physical forces—adhesion, absorption, &c.—and the force of chemical affinity.

AN ingenious method for determining the total solid matter in solution in different waters is described in *Chem. Soc. Journ.* by Dr. Mills. The method is based on the fact that if a small glass bead with an attached weight is allowed to ascend in a saline solution of known strength, it will rise more slowly, the greater the amount of solvent present. Experiments are given showing that the rate of ascent is also dependent on the nature of the soluble matter, *i.e.* on the viscosity of the solution. For detecting variations in the solids in the same water, for preparing standard solutions, &c., the bulb method is likely to be useful. Experiments detailed in the same paper lead Mills to regard the specific gravity of a potable water as a direct indication of the quantity of total solids in solution.

ANALYSES of the mud deposited round the Buxton thermal spring, by T. C. Thresh (*Chem. Soc. Journ.*), show that when dried at 120° this mud contains about 71 per cent. Mn_3O_4, with oxides of Pb, Cu, Fe, Al, Zn, Ba, Sr, Mg, and Mo, and closely agrees in composition with many specimens of "wad" or "bog manganese." Analyses of the gas evolved at the spring and of the gases dissolved in the water closely confirm those made by Playfair in 1852 : the gas evolved at the spring consists of about 99 per cent. nitrogen and 1 per cent. CO_2, that dissolved in the water of about 60 per cent. N and 40 per cent. CO_2. The water in the baths contains as much gas as could be forced into water at a pressure of 1·64 atmospheres.

A LONG and important paper by W. H. Perkin, on "Isomeric Acids obtained from Coumarin and the Ethers of Hydride of Salicyl," appears in the same number (August) of the *Chem. Soc. Journ.* Perkin has obtained two series of compounds, differing in properties, but generally convertible, one into the other, by the action of heat. He thinks that the ordinary theory of isomerism, according to which this phenomenon is traceable to the occupation of different relative positions by the atoms in two molecules, fails to explain the cases of isomerism now described by him. He favours the view that the atoms in the molecules of any two isomeric newly-described compounds occupy the same relative positions, but are at different absolute distances from each other. It is, however, to be remembered that the present theory of isomerism is applicable only to gaseous molecules ; the molecular phenomena of liquid and solid bodies are too complex to find, as yet, any general explanation. Perkin's new compounds seem to belong to this rapidly-increasing group of "physical isomerides," *i.e.* to liquid or solid bodies whose chemical properties are to be traced to the binding together of molecular groups, the individual members of which occupy relatively different positions, and which groups react as chemical units. The facts concerning molecular volumes of metameric compounds are also, on the whole, opposed to that theory of isomerism favoured by Perkin in his important paper.

A SERIES of papers on the photo-chemistry of silver bromide by Herr Eder has appeared in *Chemisches Centralblatt*. It is shown that silver bromide prepared with an excess of silver nitrate is much more sensitive towards light than when prepared with excess of potassium bromide, provided the silver bromide is disseminated through an indifferent substance, *e.g.* collodion pyroxylene. When disseminated through an easily oxidisable substance, *e.g.* gelatin or gum, silver bromide prepared with a slight excess of soluble bromide is from four to six times more sensitive than when disseminated through indifferent collodion with excess of silver nitrate. An emulsion of silver bromide in gelatin with a slight excess of the soluble bromide after several days digestion at 30°-50° becomes much more sensitive than is

Digitized by Google

other known body. Herr Eder regards the photo-chemical decomposition of silver bromide as the result of partial reduction with loss of bromine.

THE GERMAN ASSOCIATION

THE fifty-fourth meeting of the Association of German Naturalists and Physicians was held at Salzburg on September 18–24. The number of Members and Associates in attendance was 760. There were also present Foreign Members from Switzerland, the Netherlands, Russia, Denmark, and Japan. The first general meeting, on Sunday, September 18, was opened by the First Secretary, Dr. Günthner (Salzburg), who in his hearty address of welcome mentioned the fact that Salzburg was the last retirement of the celebrated physician and naturalist, Theophrastus Paracelsus. After short addresses given by the Governor and Burgomaster, Prof. Pettenkofer (Munich) read a paper "On the Soil and its Connection with the Health of Man." He pointed out that it was previously believed that the state of the air and water exerts an important influence upon the origin and propagation of epidemics, but this view could not be proved by experiments recently made. The contamination of air and water is caused by products of decomposition of bodies putrefying on or in the soil. The progress of epidemic diseases, especially of cholera, is influenced mainly by the soil. The immunity of special localities against cholera is shown by the example of Lyons, which, notwithstanding communication with infected places, remained free from cholera, though filtered Rhone water was used there. Versailles and Salzburg also were exempt from this disease. It is now generally assumed that cholera is due to the action of schizomycetes, which develop at localities where the soil is impregnated with decomposing organic bodies. The contamination is drawn up by diffusion through the porous soil into the interior of houses, where it becomes dangerous to the health of man.

On Monday the work of the sections was commenced. There were twenty-three sections, eleven of them medical. On Tuesday an excursion was made to Reichenhall (Bavaria), with its salt-mines, where the Congress was addressed by Graf Pestallozza. On Wednesday the second general meeting was held. Prof. Weismann (Freiburg-im-Breisgau) read a paper on the duration of life. After enumerating many examples of longer and shorter duration of life among animals, he pointed out that size, constitution, temper, sex, and growth are not critical for the duration of life. In general the duration of life of an individual represents the minimum of time necessary to insure the existence of the species; it is governed by adaptation and heredity. The death caused by wasting and consumption of the cells, of which the (animal) body is composed, is the result of adaptation. The capacity of unlimited life has been lost, since it has become useless. There is no death at the division of lower animals (Amœba). In higher animals the propagating cells are separated from the somatic cells; only the former preserve unlimited productiveness. The limitation of individuals in time and in space is based on the same principle. At the same meeting Prof. Meyners (Vienna) gave an address on the laws which govern human thoughts and actions. In the conclusion of his very interesting discourse, in which he mainly dealt with feelings, sensations, and the experiments of Munk and Goltz, he expressed the opinion that the phenomena of bodies do not disclose to us their essence, and that there is only a phenomenon of freedom of will. Eisenach (Thuringia) was chosen as the town in which the fifty-fifth meeting of the Association should be held.

On Thursday an excursion was organised to Zell-am-See. On Saturday the third general meeting was held. Prof. Oppolzer (Vienna) read a paper on the question: Is Newton's law of gravitation sufficient for the explanation of the motion of heavenly bodies? Are there reasons for regarding it only as approximately true? In consideration of the theories of the moon, of Mercury, and of Encke's comet, he cannot find the theories based on Newton's law in its present form sufficient, but it would suffice under the (hypothetical) assumption of a cosmic matter surrounding the sun. After an address given by Dr. Kirschensteiner (Munich), on Theophrastus Bombastus Paracelsus, the sitting was closed by Dr. Günthner. We give a list of the papers read in the sections of Natural Science.

Section II. Physics: Walter (Tarnowitz), on the molecular kinetic laws of specific heat and the heat of vaporisation of bodies in different states; Sacher (Salzburg), on a direct measure of the attraction between earth and a determined electric current; Kurz (Augsburg), on dispersion of light and measuring the index of refraction; Spörer (Potsdam), results obtained by observations of the sun; Grunmach (Berlin), on the electro-magnetic rotation of the plane of polarisation of radiant heat; Grunmach (Berlin), comparisons of mercury-thermometers with air-thermometers; Sacher (Salzburg) demonstrated some new physical experiments relating to the theory of the formation of the earth (balls of sulphur and spermaceti with crater-formations); Waltenhofen (Prague) spoke on his apparatus for demonstration of the different action of hollow and solid electro-magnets; Günther (Ansbach), on the parallelogram of forces.

Section III. Chemistry: Brühl (Lemberg), on the connection between the optic and thermic properties of liquid organic bodies; Brauner (Prague), contributions to the chemistry of the rare earths, and on the progress of the system of periodicity of elements; Schwarz (Gratz), short communication on the preparation of nearly perfect alum-cubes by a new method; Zorn (Heidelberg), on hyponitrous acid; Bernthsen (Heidelberg), on the nomenclature of the proper derivates of carbonic acid, taking special notice of isomers.

Sections IV. and V. Geology, mineralogy, palæontology, geography: Bernáth (Budapest), on the mineral waters of Hungary; Gümbel (Munich), on the geological structure of the Untersberg (near Salzburg); Hauer (Vienna) presented a new geological map of Montenegro (designed by E. Tietze); Zittel (Munich), on Spongiæ as rock-forming materials, and on Plicatocrinus; Baltzer (Zurich), on curved strata; Neumayer (Vienna), on fresh-water Conchylia from China; Alth (Krakau), on the Jurassic formation of Niczniow; Hauer (Vienna), on the Arlberg; Tschermak (Vienna), on the definition of species in mineralogy; Hoernes (Gratz), on earthquakes in general; Woehner (Vienna), on the earthquake of Agram; Richter (Salzburg), on observations made at the Obersalzbach glacier; Doelter (Gratz), on the Cape Verde Islands; Dücker (Bückeburg) on the occurrence of petroleum in Northern Germany.

Section VIII. Botany: Kraus (Triesdorf), communications on the sap-pressure of plants; De Bey (Aachen), report on five new and peculiar genera (Coniferæ) of the Aachen chalk-flora; Holzner (Weihenstephan), on agrostological theses; Hildebrand (Freiburg-im-Breisgau), some observations on the flowering and the fruits of plants; Woronin (St. Petersburg), contribution to the knowledge of Ustilagineæ; Kirchner (Hohenheim), on the longitudinal growth of plants.

Sections VIII. and IX. Zoology, comparative anatomy, entomology: Troschel (Bonn), classification of Gastropods; Fraisse (Leipsic), on cell-division and free nucleus-formation; Weidersheim (Freiburg), on the genesis of Jacobson's organ; Grobben (Vienna), on the variation of generations of Doliolum.

BIOLOGY AS AN ACADEMICAL STUDY[1]

I.

IT is told of the late Dr. Norman Macleod that, on paying his first visit in his first parish, he was peremptorily desired to sit down and "go over the fundamentals." I feel that some such demand may, not unreasonably, be made of me to-night.

Five-and-twenty years ago one's position in this respect would have been a comparatively easy one, for then biology may be said to have had no "fundamentals" at all. In spite of the labours of Buffon, Erasmus Darwin, and Lamarck, the great bulk of naturalists at that time believed in the immutability of species; as a natural consequence botany and zoology remained mere "classificatory sciences," and the extraordinary facts of comparative anatomy, of embryonic development, of geographical distribution, of palæontology, were incapable of rational explanation. Indeed, classification itself was nothing more than a logical expression of likenesses and unlikenesses, and was devoid of all real meaning.

But with the publication of the "Origin of Species," in 1859, a better day dawned for biology. The whole history of science has been a succession of attempts to bring group after group of natural phenomena within the scope of some natural law; and Charles Darwin's great service to science lies in the fact that, although not himself the discoverer of the doctrine of descent, he succeeded, by the immense array of well-arranged facts and sound generalisations contained in his epoch-making book, in

[1] Inaugural Lecture delivered in the University Library, May 2, 1881, by T. Jeffery Parker, B.Sc., Lond., Professor of Biology in the University of Otago.

Digitized by Google

bringing these natural phenomena which have to do with living things within the all-embracing law of evolution, thus making belief in the theory of special creation once for all impossible to the student of nature.

One may say then that since the publication of the "Origin of Species" evolution has taken its legitimate place as the central doctrine of biology, the key to the infinite number of problems with which the study of animals and plants brings us face to face. Without evolution these problems are incapable of explanation, and any attempt to explain them is little better than a roundabout acknowledgment of ignorance; but with the doctrine of descent as a standpoint, problem after problem yields to patient investigation, biology thereby gradually growing into a perfect and harmonious whole, as did astronomy when once the Law of universal gravitation was established.

Not that the real mystery of things is in any way diminished by this, any more than by other great discoveries. As Herbert Spencer finely says: "Positive knowledge does not, and never can, fill the whole region of possible thought. At the uttermost reach of discovery there arises, and must ever arise, the question, What lies beyond? As it is impossible to think of a limit to space, so as to exclude the idea of space lying outside that limit, so we cannot conceive of any explanation profound enough to exclude the question, What is the explanation of that explanation? Regarding science as a gradually increasing sphere, we may say that every addition to its surface does but bring it into wider contact with surrounding nescience."

But the fact that no explanation of natural phenomena can ever be final has no right to diminish our profound thankfulness for every proximate explanation which the genius of a Newton, a Dalton, or a Darwin gives us. To the true man of science these explanations come like a revelation, and he feels that his most cherished beliefs, his most ingrained prejudices, must be brought into harmony with the new light that is in him, or be cast aside as no longer tenable.

A few years ago—even at the time when this University was founded—something more than a bare statement of belief in evolution would have been required from a professor of biology giving his inaugural lecture. For then the doctrine of descent was only just emerging from the fiery trial through which all great truths, scientific or otherwise, have to pass, and it was honestly believed by many estimable persons that "Darwinism" was in direct and necessary opposition to religion and morality, and was the secret ally of atheism, socialism, and the like. But, like the fundamental doctrines of astronomy, physics, and geology, evolution has survived all attacks: I believe I am correct in saying that there is now not a single naturalist of any repute, under the age of sixty, who is not also an evolutionist; indeed, with Louis Agassiz and Von Baer, intelligent opposition to the general doctrine of transformism is practically dead.

Even among the non-scientific public, opinion has undergone a wonderful and rapid change. An evolutionist is no longer looked upon as a dangerous visionary; it is no longer thought necessary to hold "that nature's ancient power was lost" when she had to do with living things, and that the power which could form worlds out of a nebula was unable to evolve a horse from a hipparion, or even a speck of living protoplasm from the elements of the primæval sea.

Under these circumstances it would be superfluous, almost impertinent, for me to make any attempt to repeat the arguments which go to show that the animals and plants living on the earth at any period of its history are the lineal descendants of those which existed during the preceding period, and that the origin of any living thing by direct creation is, in the first place, entirely unsupported by evidence, and, in the second place, unthinkable. I proceed, therefore, to the main subject of this lecture—the position which biology should occupy in the curriculum of our schools and of our University; in other words, its place as one of the natural sciences in a rational scheme of education.

Educational subjects may be divided into two classes, the directly educational—those which serve as a true discipline, which train the mind, leading to clear thought, accurate reasoning, and a high intellectual tone; and the indirectly educational, which primarily serve to impart a certain amount of useful information, and only secondarily, by interesting the student and starting him off on a certain track of thought, serve as an actual means of mental culture. Perhaps the best examples of the two classes are furnished by mathematics on the one hand, and on the other by English history as usually taught in schools. A boy who has once grasped the idea that two and two make four [illegible] by any possibility add up anything else, has made a [illegible] in his educational career; but the boy who learns the [illegible] of Hastings was fought in the year 1066, or that [illegible] had six wives, has simply gained two comparatively [illegible] concrete facts, the possession of thousands of which [illegible] make him anything more than a well-informed person.

According to the theory of education which was [illegible] veral in the last generation—the English public [illegible] there were two educational subjects, and two only, [illegible] Latin, perhaps with "a shadowy third" in the shape [illegible] matics, but certainly nothing further than that. As a [illegible] reaction against this time-honoured method of trimming [illegible] minds to one dead level of scholarly dulness arose [illegible] private school systems, the principle of which is to pour [illegible] into a boy's head a little of all the subjects of which [illegible] posed he ought to know something when he serves [illegible] estate—divinity, Latin and Greek, modern languages, [illegible] matics, natural science, history, geography, drawing, [illegible] even bookkeeping. The wretched child is "everything [illegible] and nothing long"; his masters, chosen for knowing [illegible] of as many as possible of these subjects, are usually [illegible] superficial, and he leaves school well informed [illegible] profoundly and distressingly ill-educated.

The private school system is now, very naturally, [illegible] certain quarters a counter-reaction towards the [illegible] classical and mathematical method of education, the [illegible] that the modern plan has been tried and found [illegible] neither natural science nor any of the other recent [illegible] have any direct educational value whatever, and that [illegible] jects should therefore never form more than a very [illegible] part of either a school or a university course.

This cry for a return to the old paths has lately found [illegible] sion in an article by Dr. Karl Hillebrand,[1] who, however [illegible] certain very important concessions to his opponents. [illegible] first place, what he is fighting against is not so much [illegible] education—I mean instruction in the natural sciences—[illegible] ficial education; and in this every honest teacher of [illegible] be at one with him. Then again he advocates the postponement of the study of Latin grammar—the chief instrument of [illegible] in his eyes—to the age of twelve or thirteen, and the [illegible] ment of the first three years of high school life to [illegible] powers of "observation, comparison, memory, and all the [illegible] mentary functions of the understanding." In this also the [illegible] cate of science teaching and the opponent of the English [illegible] school system in its purity will be altogether in accordance with [illegible] Dr. Hillebrand. But when he goes on to advocate as the [illegible] training for these "elementary functions of the understanding" [illegible] the learning of texts and dates by rote, and, by way of [illegible] the "simple classifications of zoology and botany," [illegible] the "exhibition" of real animals and plants, one cannot [illegible] wish that before printing such crudities he had tried to [illegible] stand in what the elementary teaching of science really consists, [illegible] and how far such teaching would supply the training in [illegible] tion, comparison, memory, and so forth, to which [illegible] would devote the earlier years of school life. To him, as to [illegible] many, strict teaching means classical and mathematical [illegible] ling, and instruction in science is, if educational at all, [illegible] indirectly so.

This opinion as to the educational value of natural science [illegible] arises, I am inclined to think, from an utter misconception of [illegible] what is meant by science teaching: for assuming, as fact, that [illegible] science can be taught by the ordinary educational apparatus of [illegible] books and lectures. The fallacy of this is only now beginning [illegible] be perceived, even by professed teachers of science. It is [illegible] that the chemists have long had their laboratories and [illegible] human anatomists their dissecting-rooms; but the notion that [illegible] course of lectures on physics, biology, or geology is complete [illegible] without a corresponding course of practical work, is the growth [illegible] of the last few years, and is even now unrecognised in [illegible] British universities and in the large majority of schools.

And yet, one would think, nothing could be more obvious. The whole end and aim of science teaching is to bring the student into direct contact with nature; to insure his knowing as he knows his multiplication table, the main laws upon which natural phenomena depend, and to make him see, without any possibility of mistake, the relation of those laws to the facts of the universe as he is able to observe them. What would be thought of a mathematical teacher who relied entirely on lectures and [illegible]

[1] "Half-Culture in Germany," *Contemporary Review*, [illegible]

Digitized by Google

dreamed of insisting that his pupils should apply what he had taught by working out examples for themselves? Or what of a teacher of art who ignored the necessity of making his students draw or paint? Every one sees the necessity of practical, and the uselessness of exclusively theoretical teaching in these instances, yet the fact is generally ignored that the case is precisely the same with scientific subjects, and that a man who lectures to beginners day after day and year after year on, for instance, the intricacies of animal structure and the problems connected therewith, without making his students see, by actual dissection, what an animal is, is in great measure spending his strength for naught.

Until this important fact is recognised and proper provision made for it, natural science never will and never can be a power in education. As Mr. Matthew Arnold puts it, "To say that the fruit of classics, in the boys who study them, is at present greater than the fruit of the natural sciences; to say that the realists have not got their matters of instruction so well adapted to instruction as the humanists have got theirs, comes really to no more than this: that the realists are but newly-admitted labourers in the field of practical instruction, and that while the leading humanists . . . have been also schoolmasters, and have brought their mind and energy to bear upon the school teaching of their own studies, the leaders in the natural sciences . . . have not. When scientific physics have as recognised a place in public instruction as Latin and Greek they will be as well taught."[1]

When these remarks were written (in 1868) they were applicable to science-teaching not only in schools, but also, in great measure, in universities and colleges. But since that time great changes have taken place, and in biology, of which science alone I am competent to speak, the improvement is due, first of all, to my honoured master, Prof. Huxley, and next to his co-worker, Dr. Michael Foster, both of them brilliant examples of the fact that an eminent man of science may be at the same time a laborious practical teacher. The classes begun by Prof. Huxley, with the co-operation of Dr. Foster, at South Kensington, and since continued at the School of Mines by Prof. Huxley and Mr. Thiselton Dyer, at Cambridge by Dr. Foster and his pupils, at Oxford and University College, London, by Prof. Ray Lankester, have now fairly put the teaching of biology upon a sound footing, and may be said already to have proved the value of that science as a true mental discipline, an educational instrument of very high order.

At any rate this is proved as far as University education is concerned. The battle has still to be fought in the secondary schools, and, as every one must see, the circumstances there are so different that victory in the one case is no criterion of victory in the other. It is evident, in fact, that the strict training in observation and experiment, without which, I cannot insist too often, science teaching is valueless as a mental discipline, is very difficult of application in schools, and that the consequences of setting a large class of young boys to make oxygen, or take a specific gravity, or cut up a rabbit each for himself, might prove rather subversive of order than conducive to improvement. But it has been amply proved that there is no difficulty in the case of senior boys taken in comparatively small classes; and even in large classes the practical teaching of elementary botany is quite feasible, as is shown by the experience of our own High School. Botany, indeed, lends itself more than any branch of science to school-teaching, from the simple fact that by its means the pupil can be brought face to face with Nature with comparatively little trouble, with no apparatus beyond a pocket-knife, and perhaps a simple magnifying-glass, and with no mess unremovable by a duster and broom.

For these reasons I am inclined to think that botany should be made the staple science subject for the junior classes in schools. If taught thoroughly, it necessitates the introduction of a good deal of elementary chemistry and physics, since the principles of vegetable physiology, which should on no account be omitted, cannot be explained without reference to the composition of air, earth, and water, the diffusion of gases, capillarity, chemical decomposition, and so on. Theoretically, no doubt, the foundation of a scientific training should be laid with mathematics, physics, and chemistry. As to the first of these there is no difficulty; but unless the two latter can be taught practically, it seems to me that the best thing is to be content with something less than the ideally perfect, and, with mathematics as the necessary introduction to abstract science, to take as our basis for the concrete study of Nature the facts and phenomena of plant-life.[2]

There is one consideration of the first importance, which every science teacher must keep in mind if he wishes his subject to have its proper value as an educational instrument, and that is the absolute necessity for demanding as much and as hard work from his pupils as the classical or the mathematical master. Unless this is done scientific subjects must always hold an inferior position, and the teaching of them can never be followed by adequate results. It behoves every one of us to remember that—

> "Von der Stirne heiss,
> Rinnen muss der Schweiss,
> Soll das Werk den Meister loben,"

and that, if we are satisfied with a minimum of work from our pupils, we must also be content with a minimum of respect for our teaching. As long as in our Matriculation and Junior Scholarship examinations a pupil can pass creditably in a scientific subject by getting up a text-book, while to obtain distinction in classics or mathematics requires prolonged and thoughtful work, so long will science-teaching in schools fail to have any real educational value.

I should like to make it perfectly clear that I am not making the slightest attempt to uphold the absurd notion that science should replace the strict study of language and literature, or of mathematics. All that I plead for is that it should be put on equal terms with them, and should no longer be handicapped by a totally inefficient method of teaching, and then condemned as wanting in the essentials of a strictly educational subject. Those who advocate a return to purely classical instruction because of the acknowledged failure of book-science are comparable to politicians who can see no remedy for the excesses of a revolution save a return to despotism. The whole case as between scientific and literary instruction is so admirably put by Mr. Matthew Arnold that I cannot resist the pleasure of quoting the passage:—"The aim and office of instruction, say many people, is to make a man a good citizen, or a good Christian, or a gentleman; or it is to enable him to do his duty in that state of life to which he is called. It is none of these, and the modern spirit more and more discovers it to be none of these. These are at best secondary and indirect aims of instruction; its primary and direct aim is to enable a man *to know himself and the world*. Such knowledge is the only sure basis for action, and this basis it is the true aim and office of instruction to supply. To know himself a man must know the capabilities and performances of the human spirit; and the value of the humanities, of *Alterthumswissenschaft*, the science of antiquity, is that it affords for this purpose an unsurpassed source of light and stimulus. . . . But it is also a vital and formative knowledge to know the world, the laws which govern Nature, and man as a part of Nature. This the realists have perceived, and the truth of this perception, too, is inexpugnable. Every man is born with aptitudes, which give him access to vital and formative knowledge by one of these roads; either by the road of studying man and his works, or by the road of studying Nature and her works. The business of instruction is to seize and develop these aptitudes." And again: "The grand thing in teaching is to have faith that some aptitudes of this kind every one has. This one's special aptitudes are for knowing men—the study of the humanities; that one's special aptitudes are for knowing the world—the study of Nature. The circle of knowledge comprehends both, and we should all have some notion, at any rate, of the whole circle of knowledge. The rejection of the humanities by the realists, the rejection of the study of Nature by the humanists, are alike ignorant."

Until within the last few years the position of science, and especially of biology, in universities and colleges, was quite as unsatisfactory as in schools. In the days when zoology was taught merely by lectures, and a man to insure success in examinations had only to "cram" his notes or a text-book and perhaps be able to tell a mammal's skull from a bird's, or a bivalve shell from a coral, it was not unnatural for the votaries of the older forms of culture to look upon "science" as a sort of academic Alsatia—a useful-enough refuge for the stupid, the lazy, and the eccentric, but something quite

[1] "Higher Schools and Universities in Germany."

[2] For this reason I cannot but regret that in the regulations for Junior Scholarships approved by the Senate at their recent meeting, biology is only counted as of equal examination value with a single branch of physics; so that while a candidate can take up physics alone of science subjects, he is obliged, if he select biology, to take in addition either chemistry or a branch of physics or mechanics.

beneath the notice of a man with a fair share of intellect and diligence.

And this opinion was quite justified by the facts. In my own University—London—until quite recently, there was no evidence of practical knowledge required in any branch of science except botany, for the degree of Bachelor of Science. A fair amount of mathematics and mathematical physics were demanded; but the chemical standard was miserably low, and the zoology, physiology, botany, and geology were such that no experienced examinee would wish for more than a month's reading for each, with perhaps an extra fortnight in the case of botany to enable him to learn enough of the art of describing plants. But now that a searching practical examination is enforced in these subjects, the degree has a real value—it is evidence that a man has done real work.

The case is very similar at Cambridge. Formerly, the Natural Science Tripos was a bye-word—a sort of back-door to a university degree. Now, thanks in great measure to Dr. Foster, the chances are that a man who takes high honours in that Tripos will be the intellectual equal of a high wrangler or of a high classic.

Considering that this regeneration of biological teaching began only about ten years ago in London and Cambridge, I think New Zealand is distinctly to be congratulated upon the fact that the first professor of biology in the Colony—my predecessor in this Chair, Captain Hutton—was also the first to inaugurate the true method of teaching that science in the Australian Colonies. It is by no means the least important debt which the Colony owes to Prof. Hutton, that he, having made his reputation as a systematic zoologist, voluntarily undertook the labour—no light one—of organising, in connection with his lectures, a class for regular practical instruction in comparative anatomy. I must confess to a slight feeling of disappointment at finding, on my arrival here, that the revolution I had expected to initiate was already well under weigh.

(*To be continued.*)

THE ELECTRICAL DISCHARGE, ITS FORMS AND ITS FUNCTIONS.[1]

I.

IF we knew as much about electricity as we know about sound or light, we should be still a long way from having learnt all that we could wish, but we should know far more than we do now.

For instance, in the matter of sound, we know, in most cases, the nature of the air-disturbance to which it is due, and the mechanism whereby that disturbance is effected; and we have ascertained the magnitude and character of the aerial waves on which sound is carried. We know, in fact, what it is which is transmitted, and the velocity and direction in which that transmission takes place.

Again, in the matter of light, although we do not know the exact nature of the disturbance to which luminosity is due, nor the mechanical process by which that disturbance is effected; although we are not even certain whether the æthereal waves, to which light is attributed, have an actual existence or not, we nevertheless do know that something which is capable of being represented by wave motion is transmitted along a ray of light; its direction is a matter of simple observation, and we have determined the velocity with which it travels.

But when we come to electricity our knowledge is much more at fault. We know, it is true, how to produce electricity or electrical action, as well as how to transmit it, by means of wires, to a distance; we know also that there is a dissymmetry at the two ends or "terminals" of a battery or machine, or other source of electricity, implying a directional character either in that which is transmitted, or in the mode of its transmission. But we know neither what electricity really is, nor the process whereby it is transmitted. And although, on account of the dissymetry above mentioned, we cannot divest ourselves of the idea of direction, yet we have as yet no certain clue to the actual direction in which the transmission can be said to take place. It has, indeed, been shown, by the late Clerk Maxwell and others, that the mathematical expressions for the properties of a medium, whose vibrations are capable of representing the phenomena of light, are the same as those of a medium whose vibrations are capable of representing those of electro-mag-

[1] A Lecture delivered before the British Association at York on September 5, 1881, by William Spottiswoode, D.C.L., LL.D., President of the Royal Society.

netism; and that, on the assumption that the magnetic phenomenon, the w magnetic disturbances is the sa an identity in the mode of mani decide anything about the phys it even prove that the facts a lastly, even granting that there neither the mathematical form can as yet decide whether the city, is to be considered as arriving at the other, or as start at the first; or, indeed, whether sense double, in both directions.

In this somewhat unsatisfacto the subject of this evening's disc hope in any adequate sense to pose to explain what progress h of them, and to indicate the dire best promise of success in the pr

Into the various modes of pro intention now to enter. I shall most convenient, explaining only which may be of consequence periments shown in illustration fact, be assumed that electricity known means or other, and our o the course of its passage, with a v tion as to its nature and its mode

As a matter of fact we have he first, a Holtz machine, or, rathe of it), which produces electricity given off by the ordinary frictiona this by a different method; secon of metallic plates and acid, whe electricity is produced by the actio thirdly, a dynamo-machine, such Siemens, Brush, or others, which that from the battery, but by mean chanical force in moving coils or within the influence of an electro termed, within a magnetic field; by De Meritens, producing, on a pr in the dynamo-machine, a series of magnets, and in this case in alterna strument called an induction-coil, t duce from currents of one characte way to be presently described; and or condensers for accumulating larg will allow of their being discharged

Now, in the first place, suppose w or of the dynamo-machine, produce uniform current; then, if the wi closed, no directly visible effect is visible" because indirectly we can current is is a condition different to One way in which this may be show bring an ordinary piece of copper wi some iron filing, the filings are indif is in its natural state; but as soon as circuit through which a current is flow by it as if by a magnet. When the c current is interrupted, the filings drop ordinary condition. This property o is, however, beside our present purpo in order to show that the passage of without its effect on a closed circuit directly visible.

The magnetic effect which we have the only effect which a current produc in a galvanic circuit, supposed to co wire, we interpose a piece of differe refractory on account of its bad c platinum or iron, or a sufficiently thi we shall find that when the current wire becomes hot; and if we increase or reduce the thickness of the wire increase the quantity of electricity flow or diminish the size of the platinum carry it—we shall find that the temper creased. A similar increase of tempera

Digitized by Google

shortening the wire, although the explanation of the phenomenon is not quite so simple. If the same process be carried further, the platinum will become white-hot, and if it be carried still further, the platinum will be fused. The Swan, the Maxim, the Lane-Fox, and the Edison lamps, in which the light is due to the incandescence of a fine thread of carbon, are beautiful instances of the application of this principle.

The platinum, which does not allow the electricity to pass along it with the same facility as the copper, is said to offer "greater resistance" than the copper of the same thickness to the passage of the current; and if we were to measure by a suitable instrument the quantity of electricity which passed through the circuit when the platinum was interposed, and were to compare it with that which passed without the platinum, we should find that the quantity was diminished by the interposition of the platinum. The energy which, as electricity, disappears in its passage through the platinum is, however, not really lost, but reappears in the form of heat.

Instead, however, of interposing in the circuit a length of resisting metal, we may break the circuit altogether, or (to express the same thing in different words) we may interpose an interval of air. In such a case the electricity will no longer flow freely as it does through copper, or even push its way as it does through platinum, but it will traverse the interval only in a disruptive manner in the form of a flash or spark; and it is to be noted that the interval over which the passage can be made to pass, or length of spark, does not depend, at least in a direct manner, on the quantity of electricity employed or "strength of current," but rather upon the quality of it. This quality is called "tension," and it is measured by the strength of current which it can maintain, or cause to flow, through a given resistance. The force called into play in the process is called "electro-motive force." Without attempting to go fully into the subject, we may illustrate the relation of quantity or strength of current to tension or electro-motive force in general terms by reference to the instrumental means requisite for their production. Thus it is usually stated that in a battery the quantity depends upon the size of the plates employed, and the tension upon the number of cells; and similarly, that in a magneto- or a dynamo-machine, the quantity depends mainly on the thickness of the wire used in its construction, and the tension upon the number of convolutions or length of the wire in the coils for a given speed of working, or for a given number of convolutions, upon the speed at which the machine is driven.

In further explanation of this, however, it should be pointed out that the current generated has, independently of the external circuit, to pass through the cells of the battery, or through the wires of the machine, both of which offer resistance. When a strong current is required, this resistance may be diminished by increasing the size of the plates in the case of the battery, or by increasing the diameter of the wires in that of the machine. In the latter case it must be borne in mind this increase in diameter usually involves a diminution of length on account of the necessary limitations in the dimensions of the machine, and consequently also of electro-motive force. This must be compensated either by increasing the speed of the machine or by augmenting the strength of the field magnets.

With the Holtz machine the matter is a little different. The quantity of electricity produced depends on the amount of surface of the revolving plates passing in front of the collectors in a given time, and consequently for a given machine upon the speed at which it is driven. Thus there is nothing either in the construction of the machine nor in its internal working which can alter anything except the quantity of electricity produced, and we must therefore look to the circumstances and mode of discharge for a determination of the tension of the electricity evolved.

The induction-coil is an instrument for producing from currents of large quantity and low tension others of high tension, but of small quantity. It consists mainly of two parts, viz. a primary coil of thick wire and few convolutions, through which intermittent currents are sent from a battery or machine; and a secondary coil outside, but not connected with the former, of fine wire and many convolutions, through which by a kind of sympathetic or "inductive" action temporary currents are set up every time a current begins or ceases in the primary. The tension of the induced currents depends fundamentally upon the length of wire or number of the convolutions in the secondary coil. There are several other parts of the instrument which are important for its working, which, however, it is not necessary for our present purpose to particularise.

From this digression we may now return to our main subject; and taking it up again at the point where we left it, viz. the heating of resisting metals, we may vary the experiment by taking a piece of iron wire, and bringing to bear upon it some of the induced high tension currents from the induction-coil. It will now be found that if the sparks follow one another with sufficient rapidity, the wire will not have time to cool during the interval between two successive sparks, and that it will burn like a match or other combustible substance.

If, however, we use, instead of iron, some metal very difficult of fusion, or "refractory," as it is called, such as iridium, the consumption of material will be extremely small; and in the incandescent terminals we shall have a source of light of considerable power. And further, if the terminals be inclosed in an envelope impervious to air, and either well exhausted or partially filled with suitable gas other than oxygen, nitrogen for example; then the loss by oxidation will be reduced to an insignificant amount. On this principle Mr. Gordon has constructed a lamp, which consequently has, at all events, the scientific interest of occupying a position intermediate between the incandescent and the arc lamps.

Lastly, if we accumulate a large quantity of electricity in a Leyden jar, and discharge it all at once through a thin wire or film of badly conducting metal, we shall cause the metal (in this case a strip of gold leaf) to be not only fused but to be shattered or deflagrated, in the manner which you will immediately see. The image of the gold leaf is now thrown on the screen, the jar is charged by currents from the induction coil, and is discharged through the metal. The gold leaf is now shattered by the passage of a high tension charge, the quantity of which is greater than it can carry; and in the image of its remains we may trace indications of the forces which have been at work in the process of destruction. Observe, in particular, how the particles have been thrown laterally outwards, as if by an explosion from inside the gold leaf. In the alternations of range of the laterally scattered particles Mr. De La Rue traces an analogy to the phenomena of striation described below. And if these alternations are not due to diversities in the conducting power of the wire at various points, but to resistances set up periodically by the discharge itself in its passage, the two phenomena must certainly have something in common.

I do not, however, propose to pursue these forms into greater detail, because the subject to which I wish more particularly to draw your attention, as the most fruitful both in results actually obtained and in promise for the future, is the passage of the discharge through air and other gases. And I have adduced these experiments with metallic substances in order to show that the discharge through them is capable of various modifications, analogous to those which we shall presently see in gaseous media.

Turning then our attention to gases, it will be convenient, for instrumental and other reasons, to invert the order of experiments, so as to begin with the form of discharge which corresponds to the deflagration experiment, and to proceed thence to less violent forms.

We will now make use of the Holtz machine. If, while the instrument is in action, we separate the terminals to any moderate distance, the discharge will take the form of a bright spark extending usually in an irregular line from one terminal to the other. If, instead of discharging the machine or coil in this manner, we charge a Leyden jar, and then discharge it; or if, what is substantially the same thing, we insert a Leyden jar in the circuit, allowing it to become charged and to discharge itself, then the discharge is of a character similar to that above described, except that it is shorter in span, and at the same time more brilliant in illumination. This is due to the greater quantity of electricity discharged at once. It is moreover to be observed that, however great the quantity of electricity passing in this manner, the discharge appears to be absolutely instantaneous. It is moreover a curious circumstance, attested by many experiments, that the form of discharge in which a Leyden jar is used appears to be incompetent of itself to communicate heat to even inflammable bodies. Thus, such a discharge will pierce a card without leaving any signs of charring behind; and it will disperse a heap of gunpowder, through which it passes, like a heap of sand, without exploding it. It may be added that gun-cotton itself, even in a state favourable to explosion, when exposed to a discharge of this kind, is not only not ignited, but

Digitized by Google

merely shows signs of perforation like the card, without any blackening or indication of combustion. Whether these facts point merely to shortness of duration in the discharge such as to preclude the communication of heat-vibrations to the bodies traversed, or whether they imply some mode of motion with which heat has nothing to do, are questions which have been thrown out by those who have studied the subject.

In favour of the former view it should be stated that the spectrum of the spark proper, whether with or without the jar, shows bright lines, indicating the presence of metallic vapours. These of course imply a high temperature, although not necessarily any great quantity of heat. And if the duration of the spark itself be extremely small compared with that of the interval between two successive sparks, the period of cooling will be extremely long compared with that of heating, and the observed result is exactly what we might expect.

There is, however, one feature of the spark discharge proper which is perhaps especially deserving of remark, namely, the similarity, in appearance at least, of its passage with that of a spark through glass or other solid ducting substances. In the latter case we are familiar manner in which it rends its way by a shattering of the substance in its immediate path, while the parts of the substance untouched, very much as when shot through a pane of glass. The path, any considerable length, is never quite straight, divides itself into two branches. The analogy will be complete, and the phenomenon will be harmony with other known facts, if only we regard being so rapid, so instantaneous, in its passage of air have not time to exercise their mobility occupied by the spark in its passage through view, air itself in the presence of the electric regarded as exhibiting a rigidity and brittleness that of glass itself.

If, the Leyden jar having been removed, the

Fig. 1

Fig. 2.

Holtz machine be separated to a distance greater than that over which the spark will leap, a hissing or crackling noise is heard, indicating a rapid intermittence in the discharge, and a delivery, so to speak, of small quantities of electricity at a time. A minute examination of the phenomena occurring with terminals of different forms, and at different distances, has led to a classification of types of discharge under four main heads:—

1. The glow discharge: presenting a glow on the positive terminal, and a pencil of light issuing from the negative, and consisting of two portions with a dark space between them.

2. The brush discharge: consisting of a brush, viz., a stem and branches at the positive terminal, a pencil of light at the negative, and a dark space as before.

3. The band discharge: consisting of a band of light proceeding from the positive terminal, sometimes stratified, and separated from the negative glow by a dark space.

4. The spark discharge: showing in the spectroscope bright lines at both terminals. Two brushes of metallic vapour, the positive terminal being the longer, that at the negative shorter and thicker. Two dark spaces are to be noticed in form of discharge.

On the other hand, if the terminals be brought nearer than they were at first, nearer, that is to say, than to the production of the spark proper, it will be found that sharp cracking noise is replaced by a sound similar to when they were beyond striking distance. The luminosity of the discharge becomes very rapid, and its colour reddish hue.

A full explanation of this almost abrupt change in the racter of the discharge would probably involve a more acquaintance with the nature of electricity than we at possess. But there is reason to think that something following takes place:—The path between the terminals opened offers for a very short time a considerable

Digitized by Google

electricity to traverse it again. But the distance between the terminals being very small, the electricity coming from the machine soon attains the requisite quantity and tension, and the discharge is repeated before the facilities due to the preceding discharge are lost. The shortness of the interval between the terminals consequently acts in a double manner to facilitate the discharge, and thus renders the transition from one form to the other more rapid than it would otherwise have been.

FIG. 4.

FIG. 5.

Observations with the spectroscope indicate that heating here takes place, and the revolving mirror shows that either in the discharge itself, or in the heating effects due to it, there is a manifest duration, all of which tend in the direction of the explanation suggested above.

The character of the discharge from the induction-coil both when the terminals are widely separated and when they are near together, is generally similar to that from the machine; but the durational character of the former is very much more marked than that of the latter; so much so, in fact, that with large coils the duration extends over a fraction of a second, perfectly appreciable by the eye without any auxiliary apparatus. This is due to the nature of the instrument, and is dependent both upon the time occupied by the core in losing its magnetism, and also upon the mutual induction of the convolutions of the secondary coil. The flame which accompanies the spark proper is the part of the discharge which persists; and it will have been noticed particularly when the coil is excited by the De Meritens' machine. The discharge produced from the secondary through the instrumentality of this machine is so remarkable, that it has been considered worth a special study. It has also been of great assistance in the examination of the action of a magnet upon a discharge; but the results of the latter experiments have not yet been published.

The form of discharge which we have now reached is substantially that which is known as the "arc," or comparatively quiet and continuous discharge between two terminals near to one another.

Turning to the arc, let us take the form most familiar to our minds, viz. that used in electric lighting. I now project on the screen an image of the arc as used in what are called "arc lamps." The whole consists essentially of two rods of carbon placed end to end, with a short interval between them. The interval is of a length capable of being traversed by the current, at all events after the discharge has been once established. By the passage of the current, which, in fact, constitutes the arc, the carbon becomes heated to a high degree. And it is important to understand that the main source of the light is to be found, not in the arc proper, but in the heated carbons. It will be noticed that, when a machine giving direct currents is used, the two carbons are not equally heated, and that during the combustion they acquire dissimilar configurations. This dissymmetry at the terminals is found to obtain in almost every species of electrical discharge.

With the construction and outcome of the various machines employed for producing the current, and with the mechanical contrivances used for maintaining the arc at its proper length and in its proper position, we are not here concerned. All that need be here mentioned is that the carbon which would be connected with the copper element of a Grove battery, if such were used, and which is called the positive, is the one more rapidly consumed. It becomes hollowed out, and incandescent particles may be seen occasionally traversing the arc, and landing upon the second or negative carbon. In the meantime the arc proper flows steadily between the carbons, the colour being determined by the nature of the terminals, or by that of any substance placed on their ends; and partly also by the nature of the gas in which the discharge takes place.

Let us now regard the terminals merely as parts of our apparatus, subsidiary to the main purpose, and fix our attention almost exclusively on the arc itself. If we had been working in

FIG. 6.

the laboratory, I should have asked you to examine, with the aid of a microscope, the minute structure or anatomy of the arc. As it is, I must beg you to accept as a substitute for the phenomenon itself the following series of photographs, for which we are indebted to the skill and kindness of Mr. De La Rue, who has done so much with his unrivalled battery in this field of research.

Figs. 1 to 5 are, in fact, magnified representations of the discharge through air at different pressures, beginning with that of the atmosphere, and extending in a series of decreasing pressure to about one 300th part of it. In Fig. 6 the pressure has been reduced to about a 2000th part of an atmosphere. In all these instances it will be noticed that there is a tendency on the part of the luminosity to break up into disconnected blocks, and that at an early stage it begins to separate from the negative, and to cling to the positive terminal. Also, that when the pressure is considerably reduced, these blocks are replaced by the beautiful system of flakes or "striæ" delineated in the last figure of the series. At this stage the dyssymmetry on which I have already insisted is complete.

The actual length of the discharges of which you have just seen the representations, varies in a tolerably regular manner with the pressure, from half an inch to ten inches or more. From this we may gather the important fact that in the discharge through gases at low pressures we have a magnified image of the discharge at higher pressures. By this statement it is not of

Digitized by Google

course intended that every detail that is observable in the former cases can be distinguished in the latter; for the very nature of the gas, its viscosity or other properties, may prevent this. But all the characteristic features which prevail at high pressures are found also at low pressures, on a larger scale and in more marked delineation. From this consideration, as well as from others to be noticed below, we are led to the conclusion that rarefied gases form a promising field for future research into the nature of the electrical discharge.

Proceeding on this basis, I now desire to present to you the actual discharge in two or three tubes from which the air has

FIG. 7.

been exhausted in various degrees. In the first, where the pressure is that of about 3 or 4 mm. of mercury, or ·004, say one twenty-fifth part, of that of the atmosphere, the discharge takes the form of a column of light, slender in breadth and flexible in shape, extending throughout the entire length of the tube. The colour of the discharge depends on the nature of the residual gas. In the present case that gas is air; and the reddish hue is due to its constituent, nitrogen.

In the next tube the exhaustion has been carried further, viz., to a pressure of about 2 mm., or ·0026, say one-fortieth part, of an atmosphere. In this case the luminous column has become thicker; there are traces of a dark interruption towards the negative end; while beyond this break, and about the negative terminal, the light is no longer red, but of a deep blue colour. This strong contrast of colour at first sight appears inexplicable, and as a matter of fact the difficulties of explanation have not yet been altogether surmounted. But these difficulties are much diminished by a spectroscopic examination of the phenomena, from which it appears that, notwithstanding the contrast between the light near the negative terminal and that in other parts of the tube, the spectrum of the former differs from that of the latter, generally, not in its fundamental character, but mainly in the addition of certain strong lines in the blue and violet. Besides this, there is occasionally a weakening of the lines in the less refrangible part of the spectrum seen in the light of the positive column. The extension of a spectrum in the direction of the more refrangible end is known generally to depend on an increase of temperature; and as there are other grounds for attributing a higher temperature to the region near the negative terminal than to the other parts of the tube, it would seem that we must look to thermal conditions for an explanation of the contrast in question.

But, besides the contrast just described, some tubes show a diversity of colour in the same striated column. Or perhaps more strictly speaking, there coexist two, or even three, colours (usually pink and blue, with an occasional intervening green) blended together near the positive, but more separated towards the negative end. At the negative end they are in some cases completely separated; in others they are united so as to give the appearance of parti-coloured striæ. In every case, however, the blue striæ are found nearer to the negative end than the green or pink.

In the next tube the pressure is about half a mm., or roughly say one 160th part of an atmosphere; and here we find the dark space near the negative terminal, observable in the previous case, greatly increased. But besides this, the whole column no longer continuous, but is broken up into striæ with dark intervening spaces.

As the exhaustion proceeds the striæ become more and more separated, as well as individually thicker. At first mere flakes of light, they gradually increase in thickness, until they assume the proportions of blocks of light sometimes of larger dimensions in the direction of the axis of the tube than in that of the diameter. At the same time the main dark space between the head of the column and the solitary luminosity about the negative terminal, as well as the dimensions of that luminosity itself, increase in length. A dark space immediately surrounding the negative terminal, and limited by the solitary stria, also begins to show itself, and to increase with the exhaustion. This space has been named after Mr. Crookes, who first made a study of it. As we proceed yet further, the column retreats towards the positive terminal; and at the last stage the solitary luminosity shares the same fate. The Crookes' space occupies the whole tube, and no gaseous illumination whatever remains. To the phenomena which arise in this condition of things I will make allusion at a later stage.

This dependence of the distance between the striæ upon the pressure of the gas may be well illustrated by using a tube fitted at one end with a chamber containing potash. The potash has the property of absorbing gases of almost every kind, of giving them out when it is heated, and of re-absorbing them when it is allowed to cool again. This process may now be seen in actual operation.

The number and disposition of the striæ will naturally depend also on the length of the tube. The effective length may be altered without altering any other conditions of the experiment by having one terminal attached to the wire leading into the tube by a flexible spiral wire; so that the terminal itself may be shifted. At first sight it might have been supposed that the change due to an alteration in the length would have depended very much upon whether the shifting terminal is the positive or the negative. But whichever be the case, the striæ are seen to drop one after another into the positive terminal; the striæ and striæ and the adjacent dark space remain unaltered, as the change is apparent beyond a reduction in the number of the striæ.

This is, however, not the only way in which the disposition of the striæ may be made to vary. In some gases at suitable pressures an increase in the strength of the current used, or the quantity of electricity discharged through the tube, reduces the number of the striæ, and to some extent shortens the column by drawing or driving the striæ one by one into the positive terminal. In such a case it also increases their mutual distances in the same manner as if they were threaded on an elastic string. In other gases the reverse is the case. Thus, in this sulphide of hydrogen tube, the striæ in the column are numerous and crowded while the machine is in rapid motion. As the speed is diminished the striæ recede from one another, until only a few lingering specimens are left, separated by the broad dark and mysterious spaces which you now see.

The long continuance of the discharges from the induction coil afford an opportunity of examining the various phases of the striæ during their existence. The details of the instrumental arrangements, as well as other particulars of the observations, have been elsewhere described; but the main features observed may be apprehended by the illustrations subjoined.

ry-surface exposed is small, the

whole consists of, first, three or four columns of striæ of decreasing length, and afterwards of an almost unbroken field of striæ. Each of the initial columns is perfectly stratified; and the same disposition of striæ prevails throughout the entire discharge. The striæ which fill the main part of the field present a proper motion, that is a motion along the tube during their period of existence, usually steady and towards the positive. In this case it is nearly uniform, but slightly diminishing towards

, 19.—M. Wurtz in the chair.—
the foreign members of the In-
itty who were present, including
ssel, Everett, Förster, Helmholtz,

Kirchhoff, Melsens, Spottiswoode, Siemens (William and Werner), Smith, Stas, Thomson, Warren De La Rue, and Wartmann.—The following papers were read:—On the relative resistances that should be given, in dynamo-electric machines, to the active bobbins, the inductor electro-magnets, and the interior circuit, by Sir William Thomson.—On experiments made in 1826 on electric currents by lightning far from the place of observation,

Digitized by Google

and on recent studies of M. René Thury on sounds of telephones during thunderstorms, by M. Colladon. M. Thury stretched a copper wire horizontally between two houses at the height of the roofs, and connected it with the water pipes, and with two telephones. The telephones gave a characteristic sound each time and at the same instant as a flash of lightning was seen, near or far (and even when no thunder was heard). It was like the sound of a Swedish match rubbed on the box. M. Colladon, in 1826, observed deflections in a galvanometer in Paris during a thunderstorm at a distance, while there was no cloud within 30° of the zenith, and M. Peclet describes like inductive effects in his "Traité de Physique" (1832). M. Colladon thinks the sounds will be best heard in the telephone when the air is surcharged with humidity. The telephone affords an easy method of measuring the velocity of transmission of those influences.—Measurement of rotation of the plane of polarisation of light under the magnetic influence of the earth, by M. H. Becquerel. Repeating his experiments under more favourable conditions, he finds that the yellow rays D, traversing horizontally a column of 1 metre of sulphide of carbon at 0°, under the influence of terrestrial magnetism at Paris, and in a direction parallel to the declination needle, undergoes a simple magnetic rotation of 0'·8697 from right to left for an observer supposed to lie with his head towards the magnetic north. In the C.G.S. system of units this leads to the number $1·31 \times 10^{-5}$ as expressing the magnetic rotation of yellow rays through sulphide of carbon between two points of unit distance in a magnetic field equal to unity. (Mr. Gordon's figures, got by different methods, give $1·24 \times 10^{-5}$ for sodium light.)—On the passage of projectiles through resistant media, on the flow of solids and the resistance of air to the motion of projectiles, by M. Melsens. He arranged experiments with a view to catching the air carried in front of a projectile. Lead balls (about 0·017m. in diameter) were shot into a hollow cone in a block of iron, the apex being of steel, and having an opening, smaller than the ball, into a gun-barrel communicating with a bell-jar in a reservoir. The gun, the reservoir, and the bell-jar were filled with water, which was prevented escaping through the cone by a light obstacle of paper or thin brass. Detached fragments of the lead entered the gun-barrel, the bulk of the ball stopping the hole of the cone, and appearing pointed, or with an oblong drop. The effects of the penetrating air are indicated in the cracks and rupture of the gun-barrel, the bell-jar, and the bent tube between them. M. Melsens considers the resistance of the air implies factors of which artillery has not taken sufficient account. This resistance is variable throughout the trajectory, in virtue of the mass of the projectile, the form of the mass of adherent air, the velocity, the thrust of the powder-gases, up to a certain distance from the gun, and, lastly, from the very brief moment when the projectile is equally pressed in all directions by air.—On new sulphurised salts produced with sesquisulphide of phosphorus, by M. Lemoine.—On tungstoboric acid and its salts, by M. Klein.—Determination of phosphoric acid by titrated liquors, by M. Perrot.—On some of the scientific researches contained in the manuscripts of Leonardo da Vinci, by M. Ravaisson. He calls attention to a passage recommending, as a method of hearing distant sounds at sea or on land, inserting one end of a tube in the water or in the earth, and putting one's ear to the other. M. Ravaisson is preparing the manuscript B, one of twelve in the Bibliothèque de l'Institut, for publication (to follow MS. A, published in December last).

September 26.—M. Wurtz in the chair.—The following papers were read:—Researches on the gymnotus in Venezuela, by the late Dr. Sachs, by M. du Bois Reymond. At the instance of Prof. du Bois Reymond, five years ago, Dr. Sachs went out with modern electrophysiological apparatus, to study the gymnotus in the marshy waters of the Llanos of Calabozo. Returning to Berlin in 1877, he set himself to composing a work on his observations in general, and was about to write specially on the gymnotus, when he lost his life by falling down a crevasse in the Alps of the Tyrol. The monograph now presented gives the results of his studies of gymnotus, with further valuable observations by Prof. Fritsch, who has worked out the anatomy of the animal, numerous specimens of which Dr. Sachs had brought home. M. Fritsch has been able to demonstrate in an almost certain manner the development of the electric organs through metamorphosis of striated muscles.—Results obtained in treatment of phylloxerised vines by the use of sulphide of carbon and sulpho-carbonate of potassium, by M. Henneguy. The vines treated with sulphide of carbon retain their greenness longer than those treated with sulpho-carbonate of potassium, for their branches are shorter and bear fewer grapes.—Observations relative to vines treated in 1881 with sulphide of carbon, by M. Pastre. These accidents have been mostly due to excess of humidity in a compact clayey soil. The sulphide either remains liquid, or evaporates in too little space; and in both cases in the former especially) it destroys the roots. A less frequent cause is too low temperature. Among rules M. Pastre lays down are these: To treat only well-dried ground, and vines not much affected; to multiply the holes and diminish the dose; to manure well; to leave off treatment when the temperature is too low.—On trilinear forms, by M. le Paige.—Photometric comparison of luminous sources of different colours, by M. Crova. He uses a spectrophotometer. With two sources (as an electric light and a standard Carcel lamp), so placed that the mean luminosity of the two contiguous spectra is the same, the ratio the intensities of simple radiations of one light to those of the other (corresponding) is represented by a fraction greater than unity in violet, and less in red, and there is one simple radiation for which the ratio is equal to unity. If this radiation be exactly known, the measure of the ratio of its intensities in the two spectra will give *exactly* the ratio of the total intensities. M. Crova realises this with the aid of two Nicol prisms having a quartz plate between them. The apparatus gives very exact results.—Studies on the chemical action of light, by M. Lemoine. He has compared experimentally, from various points of view, the influence of light with that of heat in chemical reactions, considering, more especially, isomeric transformations, as to the influence of dissolution, temperature, organic matter, and colour. *Inter alia*, chloride of silver, so sensitive to light, is unaltered by it when dissolved in ammonia. The rate of chemical transformations often varies extremely with the temperature, for light as well as for heat. Presence of organic matters often accelerates a reaction in light and allows of its commencing at a lower temperature. For various substances which heat alone would decompose at low temperatures, the red end of the spectrum seems much less efficacious than the violet end; but in time both lights seem to produce the same effect.—Researches on tropine, by M. Ladenburg.—On a ureometer, by M. de Thierry. This apparatus, for determining the urea in urine of men and animals, is based on the process of decomposition of urine by hypobromite of soda. It is in two parts, one comprising a tube, with ampulla and stop-cock, adapted to a reservoir which communicates through a lateral tube of caoutchouc with the second part. This includes a test-tube, a graduated bell-jar, and a thermometer.—M. Larroque describes an instrument for observation of meteors; it is a mirror having the form of a double pyramid.

ANTHROPOLOGY.

AN INTRODUCTION TO THE STUDY OF MAN AND CIVILISATION.

By Edward B. Tylor, D.C.L., F.R.S.

WITH NUMEROUS ILLUSTRATIONS.

"If all manuals were like this, a generation over-educated for its intellect would have no reason to complain. . . . This volume seems to us to serve a double purpose. It is a most attractive and entertaining introduction to the science of anthropology . . . Mr. Tylor has acquired the art of teaching. . . . His writing is clear and luminous, and his arrangement masterly. . . . Mr. Tylor writes with as much caution as learning."—*Saturday Review.*

"It is an endeavour to put before the lay reader in a clear, condensed, and interesting form the main settled results of anthropological investigations into the science of man. . . . Mr. Tylor has been eminently successful in writing a very comprehensive and extremely readable book. . . . Mr. Tylor's admirable little book certainly deserves the success with which it will doubtless meet."—*Pall Mall Gazette.*

"To take in hand a chaos and reduce it to any ordinary plan; to examine the vast complex of human life in all ages and all stages, and to show how it may be treated under half a dozen main heads,—this is indeed a difficult task, yet it is one which Mr. Tylor has performed within very modest limits and with distinguished success. . . . It is neither dull nor abstract. On the contrary, every page is rich in concrete illustration and abundant colouring. Children could read the greater part of it and find it amusing, while men will find it suggestive in ideas and admirable in general arrangement. Indeed, it may be said that, slight as this little book is, Mr. Tylor has never shown his store of facts to better advantage. It is more complete and more systematic than his earlier and larger works, and it gives the results of his latest thinking in their fullest and most mature form. . . . In short, it is one of the best of the useful class of scientific works which aim at giving to the non-technical but cultivated public the best results of historical investigations as they appear to a leader of thought in the special science itself. . . . The illustrations deserve the highest praise for their fidelity and the admirable way in which they bring out the minor characteristics of race, presenting a marked contrast in this respect to most ordinary attempts at representing anthropological types. . . . On the whole Mr. Tylor's treatment of all the facts is as masterly and unexceptionable as it is simple and interesting. . . . On the whole the students who read Mr. Tylor's book may congratulate themselves upon having obtained so easy, pleasant, and workmanlike an introduction to a fascinating and delightful science."—*Athenæum.*

PRELIMINARY.

FLETCHER'S PATENT GAS FI

This arrangement utilises the strong radiant heat from the incandescent carbon in combustion of gas, requiring no asbestos or solid matter as in the ordinary gas fire. It is not only a *brilliant* gas fire, powerful stove, with a very large heating surface in the most compact form, warming and throwing large volumes of air, which can, if desired, be taken fresh from a channel leading to the outside of the

It can be used with or without a flue. If with a flue it can be used with perfect safety for heating g drying-rooms, and any other purpose where a steady heat is required without risk of gas fumes.

It is exceedingly simple. The heat, being largely pure radiant heat, is felt at once in a room to distance as that from a flaming wood fire, and the full power is felt instantly, unlike an ordinary gas requires 10 to 20 minutes to become hot.

For the same power as compared with a good gas fire the cost is less than one-half for gas, and it never any of the poisonous carbonic oxide which is so sickening and offensive in many gas fires of the ordinary co

It requires no fixing or fitting, as it stands in front of an ordinary grate, the opening of which should by a damper or plate, except a small space for the flue if used.

A number of patterns are in hand which will be pushed forward as rapidly as possible, and engravings prepared as soon as each is ready. It is expected that some if not all the patterns will be *exhibited* in a lecture on "Domestic Fireplaces," at the Smoke Abatement Exhibition at South Kensington in November.

Where gas is advisable as a fuel I believe it to be in every respect the best arrangement possible. The perfectly and instantly under control, and the gas consumption can be regulated to anything within very lar If a room is fairly ventilated a flue is hardly necessary, and, of course, as the loss of heat is absolutely neith no flue is used, it is more economical without a flue.

For Plant Houses a flue is necessary, and the stove must be in a position perfectly safe from down dr good chimney is not available the safest way is either to lead the products of combustion into a false in a room or shed not in use. As it gives a bright light it is an assistance to plants growing and blooming w winter months.

A DICTIONARY OF MUSIC AND MUSICIA

BY EMINENT WRITERS, ENGLISH AND FOREIGN.

EDITED BY GEORGE GROVE, D.C.L.

Vols. I. and II.—Price 21s. each.

Vol. I. A to IMPROMPTU. Vol. II. IMPROPERIA to PLAIN SONG.

Demy 8vo, cloth, with Illustrations in Music Type and Woodcut. Also published in Quarterly Parts to XIV. now ready, price 3s. 6d. each. Cloth Cases for binding Vols. I. and II., price 1s. each.

TO BE COMPLETED IN THREE VOLUMES.

"Dr. Grove's Dictionary will be a boon to every intelligent lover of music."—*Saturday Review.*

"What is modestly called a 'Dictionary' might have fairly been entitled an 'Encyclopædia,' for Mr G has included in his scheme everything that belongs to music, or is allied, or is even distantly related to it would be a great mistake to regard this work as useful only for the purposes of reference. It is a collec interesting and valuable articles on all kinds of musical subjects, which amateurs, who take a genuine int in the art they profess to love, will read from beginning to end."—*Daily News.*

"We now take leave of this 'Dictionary,' recommending it heartily to our readers as full of mat and amusement."—*The Times.*

"What will strike the reader first of all, perhaps, is the fulness and completeness of the informatio collected."—*Examiner.*

"As a complete account of the biographical as well as technical materials relating to the art of and its history, Mr. Grove's Dictionary is without precedent in England."—*Quarterly Review.*

"The work, when complete, will supply a want which has long been felt by amateurs and professors art in this country."—*Illustrated London News.*

"This work promises to be for music what the best encyclopædias are to general literature science."—*Guardian.*

"The excellence of the dictionary becomes more and more conspicuous as the work goes on."—*Tribune* (New York).

THURSDAY, OCTOBER 13, 1881

MR. DARWIN ON THE WORK OF WORMS

The Formation of Vegetable Mould through the Action of Worms, with Observations on their Habits. By Charles Darwin, LL.D., F.R.S. (London: John Murray, 1881.)

IF the world were not already accustomed to the unprecedented fertility of Mr. Darwin's genius, it might well be disposed to marvel at the appearance of yet another work, now added to the magnificent array of those which bear his name. But feelings of wonder at Mr. Darwin's activity have long ago been sated, and most of us have grown to regard his powers of research as belonging to a class *sui generis*, to which the ordinary measures of working capacity do not apply. Be our feelings of wonder, however, what they may, it is most gratifying to find that this latest work from the hand of our illustrious countryman is in every way worthy of its predecessors. Everywhere throughout the book we meet with the distinctive attributes of Mr. Darwin's mind. Beginning with matters of the most common knowledge, which at first sight appear to furnish the most unpromising material, he proceeds by close observation of details and sagacious manipulation of facts to establish general truths of the most far-reaching importance in directions where we should least have expected any such truths to lie.

But to avoid the presumption of seeming to commend the work of so great a master, we shall proceed at once to render an epitome of the work itself. This, as its title is sufficient to denote, is an extension of the celebrated paper "On the Formation of Mould," read before the Geological Society in 1837 (See *Trans.* Geol. Soc. vol. v. p. 505); but the extension is so considerable that the present volume is really a new work. The subject, of course, is the same; but the later observations, while tending to confirm, and in fact to demonstrate, the conclusions based upon the former, have served to swell a short paper into a book of over 300 pages. Alluding to this paper, Mr. Darwin writes:

"It was there shown that small fragments of burnt marl, cinders, &c., which had been thickly strewed over the surface of several meadows, were found after a few years lying at a depth of some inches beneath the turf, but still forming a layer. This apparent sinking of superficial bodies is due, as was first suggested to me by Mr. Wedgwood, of Maer Hall, in Staffordshire, to the large quantity of fine earth continually brought up to the surface by worms in the form of castings. These castings are sooner or later spread out, and cover up any object left on the surface. I was thus led to conclude that all the vegetable mould over the whole country has passed many times through the intestinal canal of worms. Hence the term 'animal mould' would be more appropriate than that commonly used of 'vegetable mould.'"

Dealing next with criticisms which from time to time have been made upon his original paper, Mr. Darwin quotes one from Mr. Fish, which we may here re-quote on account of its instructive character. "Considering their weakness and their size, the work they are represented to have accomplished is stupendous." On which Mr. Darwin observes:—"Here we have an instance of that inability to sum up the effects of a continually recurring cause, which has often retarded the progress of science, as formerly in the case of geology, and more recently in that of the principle of evolution." He then adds:—

"Although these several objections seemed to me to have no weight, yet I resolved to make more observations of the same kind as those published, and to attack the problem on another side; namely, to weigh all the castings thrown up within a given time in a measured space, instead of ascertaining the rate at which objects left on the surface were buried by worms. But some of my observations have been rendered almost superfluous by an admirable paper by Von Hensen, already alluded to, which appeared in 1877. Before entering on details with respect to the castings, it will be advisable to give some account of the habits of worms from my own observations and from those of other naturalists."

Of these habits the most interesting are as follows:—

Although earth-worms are properly speaking terrestrial animals, they are still "like the other members of the great class of annelids to which they belong," semi-aquatic. For while dry air is quickly fatal to them, they may live when completely submerged in water for nearly four months. Normally they live in burrows, and generally lie motionless just at the mouth of the latter, so that by looking down into the burrows the heads of the worms can be seen. This habit of lying near the surface leads to their destruction in enormous numbers by birds. For,

"Every morning during certain seasons of the year, the thrushes and blackbirds on all the lawns throughout the country draw out of their holes an astonishing number of worms; and this they could not do unless they lay close to the surface. It is not probable that worms behave in this manner for the sake of breathing fresh air, for we have seen that they can live for a long time under water. I believe that they lie near the surface for the sake of warmth, especially in the morning; and we shall hereafter find that they often coat the mouths of their burrows with leaves, apparently to prevent their bodies from coming into close contact with the cold damp earth. It is said that they completely close their burrows during the winter."

As regards powers of special sense, it has been observed by Hoffmeister that, although destitute of eyes, earth-warms are sensitive to light, time however being required for the summation of the stimulus before it is responded to. It is only the anterior extremity of the body, where the cerebral ganglia are situated, that is thus sensitive to light. These observations have been confirmed by Mr. Darwin. He further found that the colour of the light apparently made no difference in the result, nor did partly filtering out the heat-rays by means of a sheet of glass; while a dull-red heated poker, held at such a distance from the worms as would cause a sensible degree of warmth to the hand, did not disturb them nearly so much as the light from a candle concentrated by a lens. The sensitiveness to light is less when a worm is engaged in eating or in dragging leaves into its burrow—a fact which Mr. Darwin is disposed to consider analogous to what in higher animals we know as the distracting influence of attention. When not engaged in any active operation, the sensitiveness of worms to light is so considerable that "when a worm is suddenly illuminated it dashes like a rabbit into its burrow."

With respect to hearing, all the experiments went to show that worms are totally deaf to all kinds of aërial vibration, although extremely sensitive to the vibration of

Digitized by Google

any solid object with which they may be in contact, as was shown, among other ways, by placing flower-pots containing worms in their burrows upon a piano; on striking single notes, whether high or low, the worms instantly retreated. In this connection, also, the following may be quoted:—

"It has often been said that if the ground is beaten or otherwise made to tremble, worms believe that they are pursued by a mole, and leave their burrows. I beat the ground in many places where worms abounded, but not one emerged. When, however, the ground is dug with a fork and is violently disturbed beneath a worm, it will often crawl quickly out of its burrow."

Regarding smell, the interesting result was obtained, that the sense is "confined to the perception of certain odours"—namely, those emitted by natural food. For while the animals showed themselves indifferent to tobacco-juice, paraffin, &c., held near them, pieces of cabbage-leaf, onions, &c., when buried near an earthworm, were always discovered by the animal.

The presence of taste was proved by the fact that the worm showed a preference for some varieties of cabbage over others; but "of all their senses, that of touch, including in the term the perception of vibration, seems much the most highly developed."

Worms are omnivorous, dragging pieces of meat as well as leaves into their burrows for the purpose of eating them. They smear the leaves so drawn in with a secreted fluid. This fluid is alkaline, and acts both on the starch granules and on the protoplasmic contents of the cells; it thus resembles in nature the pancreatic secretion, and serves partly to digest the leaves before they are taken into the alimentary canal—so constituting the only case of extra-stomachal digestion hitherto recorded in an animal—its nearest analogy being perhaps that of the digestive fluid of Drosera or Dionœa, "for here animal matter is digested and converted into peptone not within a stomach, but on the surface of the leaves."

We now come to one of the most interesting chapters, which deals with the habit of dragging down leaves, &c., into the burrows; for here the experiments elicited some very remarkable evidence of action which is apparently intelligent. These experiments are thus led up to.

"Worms seize leaves and other objects, not only to serve as food, but for plugging up the mouths of their burrows; and this is one of their strongest instincts. Leaves and petioles of many kinds, some flower-peduncles, often decayed twigs of trees, bits of paper, feathers, tufts of wool and horse-hairs are dragged into their burrows for this purpose. . . . When worms cannot obtain leaves, petioles, sticks, &c., with which to plug up the mouths of their burrows, they often protect them by little heaps of stones; and such heaps of smooth rounded pebbles may frequently be seen on gravel-walks. Here there can be no question about food. A lady, who was interested in the habits of worms, removed the little heaps of stones from the mouths of several burrows and cleared the surface of the ground for some inches all round. She went out on the following night with a lantern, and saw the worms with their tails fixed in their burrows, dragging the stones inwards by the aid of their mouths, no doubt by suction. 'After two nights some of the holes had eight or nine small stones over them; after four nights one had about thirty, and another thirty-four stones.' One stone which had been dragged over the gravel-walk to the mouth of a burrow weighed two ounces; and this proves how strong worms are."

The object of this plugging Mr. Darwin ass
that of "checking the free ingress of the in
of air when chilled by radiation at night."

Now, concerning the apparent intelligence
these plugging operations, Mr. Darwin "sh
fully how worms dragged leaves into the
whether by their tips or bases or middle parts
more especially desirable to do this in the ca
not natives to our country; for although t
dragging leaves into their burrows is unq
stinctive with worms, yet instinct could not re
to act in the case of leaves about which they
knew nothing. If, moreover, worms acted m
instinct or an unvarying inherited impulse,
draw all kinds of leaves into their burrows i
manner. If they have no such definite instinct
expect that chance would determine whether t
or middle was seized. If both these alternati
cluded, intelligence alone is left; unless di
each case first tries many different methods,
that alone which proves possible or the most
to act in this manner and to try different meth
a near approach to intelligence."

A large number of experiments were there
with leaves of various shapes, and both of en
exotic species. The results showed unequiv
the part of the leaf which the worm seized for d
of dragging the whole into the burrow was ne
of chance, but in an overwhelming majority of
part of a leaf was seized by the dragging of
leaf would offer least resistance to being drawn
burrow. Thus, for instance, "the basal marg
blade in many kinds of leaves forms a large a
the foot-stalk; and if such a leaf were drawn
foot-stalk, the basal margin would come alm
contact with the ground on each side of the hol
would render the drawing in of the leaf very
Nevertheless worms break through their habit of
the foot-stalk, if this part offers them the most ea
means for drawing leaves into their burrows."

Again, in the case of pine-leaves consisting
needles joined to a common base, it is almost in
by this base that the worm draws in the pair of
and it is evident that, as the worm cannot lay hol
two diverging points at the same time, this is
part of the leaf by seizing which they would be
drag the whole into their burrows. Mr. Darwin
some leaves tying or cementing the two diverging
together; but the worms still preferred the base.
further to test the hypothesis of chance, simple
angles were cut out of paper and given to the
instead of leaves. Here "it might certainly have
expected, supposing that worms seized hold of th
angles by chance, that a considerably larger prop
would have been dragged in by the basal than
apical part"; while, inasmuch as the latter was in
sense the thin end of the wedge, it was the part
intelligent action would be most likely to choose.
results of many experiments with these paper ang
showed that "nearly three times as many were dra
by the apex as by the base. . . . We may fairly
conclude that the manner in which the triangles
drawn into the burrows is not a matter of chance."

Digitized by Google

and we may infer—improbable as is the inference—that worms are able by some means to judge which is the best end by which to draw triangles of paper into their burrows."

On the question of defining such action as intelligent or non-intelligent, Mr. Darwin refers to the criterion "that we can safely infer intelligence only when we see an individual profiting by its own individual experience"; and he adds that "if worms are able to judge, either before or after having drawn an object close to the mouths of their burrows, how best to drag it in, they must acquire some notion of its general shape," and thus guide their actions by the result of individual experience.

Assuredly these observations are most interesting, and it would seem well worth while to try whether, by a series of lessons with similar triangles of paper, an individual worm could be taught to lay hold of the apex in a greater and greater proportional number of cases; if so, there could no longer be any question as to the intelligent nature of the action.

The only other observations with which we are acquainted pointing to the existence of intelligence in annelids are those of Sir E. Tennant ("Natural History of Ceylon," p. 481).

The remaining chapters of the book are occupied with the subject of its title, and in their course many quantitative results are given of the amount of mould which worms are able to cast up. Thus, for instance, a certain field was thickly covered with marl. Twenty-eight years afterwards this layer of marl was found buried by mould to a depth varying between twelve and fourteen inches. Several other similar cases are given, the most interesting being that of a field which adjoins Mr. Darwin's own house. This was last ploughed in 1841, then harrowed, and left to become pasture land. Then

"For several years it was clothed with an extremely scant vegetation, and was so thickly covered with small and large flints (some of them half as large as a child's head) that the field was always called by my sons 'the stony field.' When they ran down the slope the stones clattered together. I remember doubting whether I should live to see these larger flints covered with vegetable mould and turf. But the smaller stones disappeared before many years had elapsed, as did every one of the larger ones after a time; so that after thirty years (1871) a horse could gallop over the compact turf from one end of the field to the other, and not strike a single stone with his shoes. To any one who remembered the appearance of the field in 1842, the transformation was wonderful. This was certainly the work of the worms, for though castings were not frequent for several years, yet some were thrown up month after month, and these gradually increased in numbers as the pasture improved. In the year 1871 a trench was dug on the above slope, and the blades of grass were cut off close to the roots, so that the thickness of the turf and of the vegetable mould could be measured accurately. . . . The average accumulation of the mould during the whole thirty years was only 083 inch per year; but the rate must have been much slower at first, and afterwards considerably quicker."

Numberless other corroborative cases are given, but we have no further space to enter into their details. Large stones are slowly undermined and sunk by worms, and woodcuts are given to illustrate actual measurements made by Mr. Darwin or his sons of the rate of sinking in particular cases. These measurements show that in the course of two or three centuries large blocks of stone (*e.g.* 67 × 39 × 15 inches) may become completely buried. Thus we are not surprised to learn that old pavements and low walls are subject to the same process, and many instances are given which have been observed by Mr. Darwin or his sons of the remains of Roman houses buried so far beneath the soil that the latter has been ploughed for years without any one having suspected the presence of walls and pavements beneath. In some cases the thickness of the mould or soil above such remains was found to be twenty, thirty, and even forty inches.

The actual weight of worm-castings thrown up in one year was calculated in one case to amount to 18·12 tons per acre.

Such being the work that worms are able by their gradual and cumulative action to accomplish, it becomes evident, as pointed out in Mr. Darwin's paper more than forty years ago, that worms must play an important part in the process of denudation. This topic is therefore treated at length, and it is shown that over and above the mechanical action already described, worms materially assist the process of denudation by the chemical actions incidental to digestion. For

"The combination of any acid with a base is much facilitated by agitation, as fresh surfaces are thus continually brought into contact. This will be thoroughly effected with the particles of stone and earth in the intestines of worms, during the digestive process; and it should be remembered that the entire mass of the mould over every field, passes, in the course of a few years, through their alimentary canals. Moreover as the old burrows slowly collapse, and as fresh castings are continually brought to the surface, the whole superficial layer of mould slowly revolves or circulates; and the friction of the particles one with another will rub off the finest films of disintegrated matter as soon as they are formed. Through these several means minute fragments of rocks of many kinds and mere particles in the soil will be continually exposed to chemical decomposition; and thus the amount of soil will tend to increase."

And,

"The several humus-acids, which appear, as we have just seen, to be generated within the bodies of worms during the digestive process, and their acid salts, play a highly important part, according to the recent observations of Mr. Julien, in the disintegration of various kinds of rocks."

Further,

"The trituration of small particles of stone in the gizzards of worms is of more importance under a geological point of view than may at first appear to be the case; for Mr. Sorby has clearly shown that the ordinary means of disintegration, namely, running water and the waves of the sea, act with less and less power on fragments of rock the smaller they are."

This assistance which worms lend to the process of denudation is of special importance in the case of flat or gently-inclined surfaces, for here it is not improbably the chief agent at work. Castings thrown up during or shortly before rain flow for a short distance down an inclined surface, and the finest earth is washed completely away. Again, during dry weather, the disintegrated castings roll as little pellets, and a strong wind blows all the castings, even on a level field, to leeward.

One other observation must be quoted, which, besides

Digitized by Google

being of interest in itself, also has reference to the important subject of denudation :—

"Little horizontal ledges, one above another, have been observed on steep grassy slopes in many parts of the world. Their formation has been attributed to animals travelling repeatedly along the slope in the same horizontal lines while grazing, and that they do thus move and use the ledges is certain; but Prof. Henslow (a most careful observer) told Sir J. D. Hooker that he was convinced that this was not the sole cause of their formation."

It is then shown that the initial cause of these ledges is the burrowing of earthworms. For,

"If the little embankments above the Corniche Road, which Dr. King saw in the act of formation by the accumulation of disintegrated and rolled worm-castings, were to become confluent along horizontal lines, ledges would be formed. Each embankment would tend to extend laterally by the lateral extension of the arrested castings; and animals grazing on a steep slope would almost certainly make use of every prominence at nearly the same level, and would indent the turf between them; and such intermediate indentations would again arrest the castings."

Thus, on the whole, it will be seen how important an agency in nature Mr. Darwin has shown the action of worms to be, so that, in his own concluding words, "it may be doubted whether there are many other animals which have played so important part in the history of the world as have these lowly organised creatures."

GEORGE J. ROMANES

OUR BOOK SHELF

The Atlas-Geography. By A. H. Macdonell. (London: H. K. Lewis, 1881.)

UNDER this title Mrs. Macdonell has attempted to supply what she believes to be a want long felt in teaching geography to young children. She finds, as every teacher finds, that children prefer the map to the book, and so she provides the means of teaching geography by means of an atlas. The Atlas-Geography consists of nine double maps. First we have in each case a coloured map with the leading names filled in, and facing it a list of the leading features in the map, countries, their divisions, towns, oceans, islands, capes, rivers, &c., which the children learn by heart, fixing at the same time their positions on the maps. Following this is a corresponding uncoloured map, without names, on which the children should be able to point out the features without assistance. Facing this is an interesting and simple descriptive account of the leading characteristics of the continent or country to which the map refers. It will thus be seen that in the hands of a painstaking and judicious parent or teacher the Atlas-Geography ought to prove a most valuable help in interesting children in the subject, and in enabling them to acquire the leading facts. The maps are well executed, clear, and not over-crowded; they are the World, Europe, Asia, Africa, Australia, North America, South America, the British Isles, and Palestine.

Gesammelte Abhandlungen und kleinere Schriften zur Pflanzengeographie. The collected treatises and shorter writings on Phytogeography of the late A. Grisebach, edited by his son, Dr. Ed. Grisebach. 8vo, pp. 628. (Leipzig: Wilhelm Engelmann.)

AS the editor states in his preface, the present volume combines for the first time the numerous writings on phytogeography of the late Prof. A. Grisebach, spread over a period of thirty years, and scattered in various journals and publications, several of them very difficult of access. Constant reference is made to many of these writings in the "Vegetation der Erde" (1872); hence their publication in a collected form is a great boon. In addition those article published previous to the "Vegetation der Erde," this volume contains the author's subsequent reports (1866-76) on the progress in the geography plants. It also contains a biographical sketch of the Prof. Grisebach, together with the bibliography of works. An excellent French translation of the "Vegetation der Erde" appeared in 1874, but no English tion has been published, nor would we recommend publication of one now, because the data that have been accumulating during the last decade would justify publication of an original work, treating the subject from a different standpoint. W. B. H.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.

The Solar Outburst of July 25, 1881

IN the interesting account of a solar outburst on July contained in your last number (p. 508), Mr. Hennessey says that "unhappily the sun remained invisible till July Referring to our sketches of the solar surface, I find that nearest in time to the date of the outburst are those on July 21 and 27. On the intervening days clouds prevented all solar work. The sketch on July 21 shows the group in the [*n p*] quarter of Mr. Hennessey's disk, and that of gives those in the [*n f*] and [*s f*] portions, and also the groups in the [*n p*] which were farthest from the centre on the 21st. There was certainly not the slightest trace on the 21st the remarkable group which burst forth so suddenly on the and there can be very little doubt that the spots in the quarter on the 27th are identically the same as those in the quarter on the 21st. Drawings of the solar disk are made on every available day, and the position of each spot is measured with the greatest exactness; but when the sky is cloudy, as the 27th, it is not always possible to fill in all the details exact position of each spot is invariably marked before details are sketched, and therefore, as the definition on the was good, the group, which suddenly appeared near the edge of the disk on the 25th, must already have completely crossed I might mention, in conclusion, that our magnetic photographs show no sign of any disturbance synchronous with the outburst.

S. J. PERRY

Stonyhurst Observatory, Whalley, September 30

On the Velocity of Light

WITH reference to Lord Rayleigh's article on the Velocity Light (vol. xxiv. p. 382) I, and possibly others, find it difficult to follow him when he says, in the case of all the methods determination of the velocity of light except the aberration method, that the velocity arrived at is the "group velocity," not necessarily the "wave velocity." I, for one, should be of further exposition. Does not Foucault's revolving mirror experiment, for instance, measure the velocity of motion of centre of the disturbance which is transmitted from the mirror? And would it not be the case that, if the waves ran faster than the groups, new groups would be continually forming ahead, the old ones dropping out behind: so that the centre the disturbance would not remain in any given group? Is there any credence to be given to the result that blue light travels anything like 1·8 faster than red light, while this is unproved by the colours of Jupiter's satellites?

W. H. MACAULAY

Mountsorrel, August 29

An Aquatic Hymenopterous Insect

THE following circumstance may prove interesting, as probably new, to some of your entomological readers. On the

Digitized by Google

ber 10, in a gathering of pond-water made in this neighbourhood and brought home for microscopical examination, a somewhat singular and unusual object presented itself, but speedily making its way to the sediment at the bottom, it became lost to sight. Upon the evening of the 12th, or after the lapse of fully two days, while holding the bottle to the light, the same object again appeared, swimming or flying in mid-water with a peculiar jerky movement resembling that of some of the Entomostraca, and for one of which I at first mistook it. On removal by means of a dipping-tube to a zoophyte trough for fuller examination, it proved, to my great surprise, to be one of the small Hymenopterous flies of the Proctotrupid family, and here it continued its active movements, now walking and running upon the bottom and sides of the trough, now flying, as it were, through mid-water by the energetic movements of its wings, but apparently making no effort to escape. Examination thus proving no easy task while living, and fearing the loss of a specimen of habits so unique, I decided upon securing it permanently as a microscopic mount. With a minute description I need not now trouble you, but as neither in Westwood nor in any other of the authorities on such subjects at my command I can find any record of this singular fact having been hitherto observed, either in connection with the parasitic Hymenoptera or any other similar insects in the perfect state adapted apparently to an aërial life alone—that they should quit their natural habitat for so lengthened a sojourn in the water—I would make the inquiry as to whether any like occurrence has been noted by any of your other correspondents. EDWIN POSTOCK

Stone, October 6

[Our correspondent has had the good fortune to re-discover in this country the little Hymenopterous insect found almost simultaneously by Sir John Lubbock and Mr. Duchess in 1862, to which the former applied the name *Polynema natans* (*Transactions* of Linnean Society, vol. xxiv. part ii. p. 138, 1863). The insect is parasitic in its larval stage *in the eggs of dragon-flies*. A brief summary of its peculiarities is given in Lubbock's "Origin and Metamorphoses of Insects" (Macmillan and Co., 1874). More recently Prof. Westwood has suggested (*Transactions* of Linnean Society, second series, "Zoology," vol. i. part viii. p. 584, 1879) that the insect is scarcely a true *Polynema*, but rather an *Anaphes*, or the type of a new genus. A true Ichneumon (*Agriotypus armatus*) has long been known to be parasitic in caddis-worms, and therefore also aquatic in its habits.—ED.]

Practical Physics for Boys

IN Prof. Parker's very valuable and interesting paper (vol. xxiv. p. 543) he says: "The consequences of setting large classes of young boys to make oxygen, or to take a specific gravity . . . each for himself, might prove rather subversive of order than conducive to improvement." It may be interesting to some of your readers to know that at Clifton College we have lately tried the experiment of turning some of our ordinary physics classes, numbering from twenty-four to thirty boys, bodily into the physical laboratory, where they work at weighing, measuring, finding specific gravities and such matters, under the control of a single master. The boys work in pairs, each with a little manual of instruction, and each pair with a separate cupboard of cheap apparatus. Two such classes are taken by Mr. Worthington and myself, and we are both agreed that whatever difficulties we may feel, we have none in the matter of discipline. On the contrary, the boys are with scarcely an exception most keen and eager at this work. I understand that similar classes in practical chemistry will shortly be set on foot by Mr. Shenstone in our chemical laboratory. H. B. JUPP

Clifton College

A New Comet

I OBSERVED a telescopic comet in Leo on the mornings of October 4, 5, 6, and 10. The rough positions, as I estimated them, were R.A. 9h. 22m., Dec. 16° N. on the 4th, and R.A. 9h. 36m., Dec. 15° N. on the 10th. The motion is about 30′ daily eastwards. When the present bright moonlight is gone the comet will be a fairly bright object in the telescope. At the end of the present week it must be looked for immediately preceding η Leonis.

When I saw it first, on the morning of October 4, it looked like a bright nebula, and I cannot understand how I missed it on the mornings of September 29 and October 1, when I had carefully swept the same region for several hours before sunrise. The inference is that it is getting brighter. W. F. DENNING

Ashley-Down, Bristol, October 10

A Kinematical Theorem

SOME little time ago Mr. Kempe published in NATURE a theorem of interest in kinematics. I subsequently stated in the same pages that this theorem and all theorems of uniplanar kinematics are most simply and properly proved from the consideration that epicycloidal motion is the basis of all uniplanar motion—and that this is also the proper principle on which to base the theory of planimeters. It may not be out of place to occupy a few lines in NATURE with another curious kinematical theorem allied to Kempe's, which I have just found by this method. *If a plane*, A, *move about in any manner over a fixed plane*, B, *and return to its original position after any number of revolutions, all those right lines in the plane* A *which have enveloped glisettes of the same area, are tangents to a conic, and by varying the area of the glisette we obtain a series of confocal conics.* I use the term *glisette* under protest—"line roulette" would be better, as the former name is more applicable to a curve of another sort. Integrating Anemometer

MY attention was called to a letter on this subject in your issue of the 29th ult. (vol. xxiv. p. 510), though not in time to enable me to answer it last week. I take this opportunity of stating that the gentleman to whom the idea of the instrument was originally due, and who has defrayed the whole cost of its construction, is the Rev. J. M. Wilson, M.A., head-master of Clifton College (not Dr. Wilson, as mis-stated in the Association *Journal* at York and in your abstract). The objection that the air does not move "parallel to itself," by which I presume is meant in planes parallel to its general direction, does not apply to this any more than to any other cup anemometer. Only the horizontal component of the wind's velocity is sought, and this is given with tolerable accuracy. I have no means of knowing to what extent Mr. Burton's integrator resembles the anemometer in question, but it should be noticed that the two instruments are of a different kind and for a different purpose. Mr. R. Scott was in the chair when the paper was read at York, and joined in the discussion. Prof. Stokes was also present, and has since been in correspondence with me on the matter. Neither of these gentlemen, however, mentioned any other instrument as at all resembling it; indeed upon its being compared to that of Dr. von Oetlinger, Mr. Scott took occasion to point out at least one important difference, viz. the cost. H. S. HELE SHAW

Infusorial Parasites on Stickleback

MR. N. H. POOLE (NATURE, vol. xxiv. p. 485) is apparently right in anticipating that he has discovered either a new habitat for *Trichodina pediculis* or a new representative of that infusorial genus. Although hitherto regarded as a parasite only of the fresh-water polypes, *Hydra vulgaris* and *H. viridis*, I have recently obtained specimens of the type in question living as a parasite, or rather a commensal, on the branchial appendages of the larva of the common newt, *Triton cristatus*. An allied, but marine species, *Trichodina scorpæna*, has been recently described by Prof. Ch. Robin, that infests in a similar manner the branchia of fishes belonging to the genera *Trigla* and *Scorpæna*, and a further search will no doubt reveal a yet more extensive distribution of the Urceolariadæ, including *Trichodina*, among the Piscine race. Mr. Poole will find full particulars of the data here referred to, together with an account and illustrations of all the forms so far relegated to this somewhat remarkable infusorial group, in Part V., p. 645 *et seq.*, of my "Manual of the Infusoria," just published. W. SAVILLE KENT

The Dark Day in New England

REFERRING to your paragraph in last week's NATURE (p. 540) about the remarkable phenomenon which occurred in New England on September 6, I find in the recently-published "History of Lynn, Massachusetts," the following:—

"1716.—Extraordinary darkness at noonday October 21st; dinner tables lighted."

"1780.—Memorable dark day May 19th; houses lighted as at night." CHARLES W. HARDING

Lynn, October 7

THE EVOLUTION OF THE CRYPTOGAMS[1]

II.

THE direction and many of the gradations through which the highest classes of the vegetable kingdom have been developed from the lower are preserved in the palæontological record. In order to decipher them, however, certain facts must be kept in view: chiefly, that the higher and more complex organisations, are the most susceptible to changes in the external conditions upon which they are dependent, and therefore more readily destroyed, while the simpler the organisation the more yielding or plastic it is, and the greater the chance that it will be able to survive by adapting itself to change. Thus the superb Cryptogams of the Carboniferous succumbed no doubt to great physical changes, but the more humble of them bent to the new conditions, and even found therein an impetus leading to unexpected developments which eventually carried them far beyond their more advanced brethren.

Tracing back the origin of vegetable life, we see that it consisted nearest its source solely of Algæ. A little later, Cryptogams appeared, and developed their maximum during the Palæozoic period. Next, almost synchronously, Gymnosperms are met with, and after a long time preponderate; and then Angiosperms, obscure and subordinate at first, begin, towards the close of the Secondary period, to take the first rank.

Most of the lowest Algæ, such as Ulva and Confervæ, are scarcely of a texture to have left traces of their existence, but eight still existing Diatoms have been discovered in British Coal.

The next group, morphologically, of Algæ—the Siphoneæ—have been shown by M. Munier-Chalmas to be

FIG. 1.—*Bilobites furcifera*, d'Orb. Part of a "Phyllome," with traces of expansions and ramifications; half natural size. Silurian of Bagnols

abundant in the Trias and Secondary rocks, and to be analogous, or perhaps identical, with the existing Cymopolia and Acetabularia. It is unfortunate that, owing to the texture of most of the Algæ, observation has to be concentrated on the few groups that could be preserved. In the Silurian the remains of these are numerous, and of forms completely differing from existing types.

Following the primordial Palæozoic forms, there appear successively the more highly organised Groups, Characeæ in the Trias, Laminariaceæ in the infra-Lias, and finally Fucaceæ in the Eocene.

The Mosses and Liverworts, which seem to indicate the stages through which Algæ gradually became adapted to terrestrial conditions, are unknown in the older rocks; yet, far from assuming that they did not then exist, we should rather consider how exceedingly unfavourable are the conditions under which marine and estuarine strata are deposited to the chance of their becoming imbedded.

The order Calamareæ, as the authors prefer to call the Equisitaceæ, include such diverse types as Calamites, Annularia, Asterophyllites, and Equisteum, though Camalodendron and a few other forms are excluded. The group is characterised by the arrangement of their organs in whorls, whether these are true leaves or the modified leaves which support the sporangia. The sporangial whorls either occur together and form a terminal fruit, or are placed alternately with whorls of true leaves, and the sporangial bracts are either distinct or coalesce to form a sheath. Modifications of one

Continued from p. 75.

Digitized by Google

other of these characters are the foundations of all the Palæozoic genera yet known. In the extinct Carboniferous forms the fertile or sporangial whorls alternated with, and were protected by, the overlapping whorls of barren leaves, while in Equisetum the sporangial whorls are naked and clustered in a terminal spike, an arrangement considered by Saporta and Marion to be more favourable to the dispersion of the spores. Annularia and Asterophyllites were floating or procumbent plants. Calamites strongly resembled the existing aquatic Equisitaceæ, though ex-

FIG. 2.—*Bilobites Vilanova*, Sap. and Mar. Base of a "Phyllome." Silurian of Andalusia.

ceeding them twenty times in size, and surpassing them in development by the possession of spores of two sexes. Their more complex structure and consequent inadaptability to changed conditions, favoured, the authors believe, their early extinction in the Permian. In the Trias, and until the Jurassic, several slightly modified genera coexisted with true Equisetum, and the survival of the latter, one of the genera that have persisted almost unchanged from the Carboniferous, is probably due to their simple

FIG. 3.—Prothallus of an Osmunda aged eight months, slightly magnified to show the double row of archegones down the centre.

organisation, easy dispersion of the spores, and the immense depths to which their rhizomes penetrate.

The structure of ferns, unlike that of Equisitaceæ, lends itself to infinite diversity. The fronds may be simple or multipartite, without their form implying the slightest degree of relationship, and supposed alliances between fossil and recent ferns, such as Ettingshausen has based upon the aspect and venation of the frond, are declared by the authors to be valueless and misleading.

The earliest ferns had simple fronds, and probably resembled in their vegetative organs the Hymenophylleæ, a group already well represented in the Carboniferous. Next in order come the Osmundaceæ, if the relative

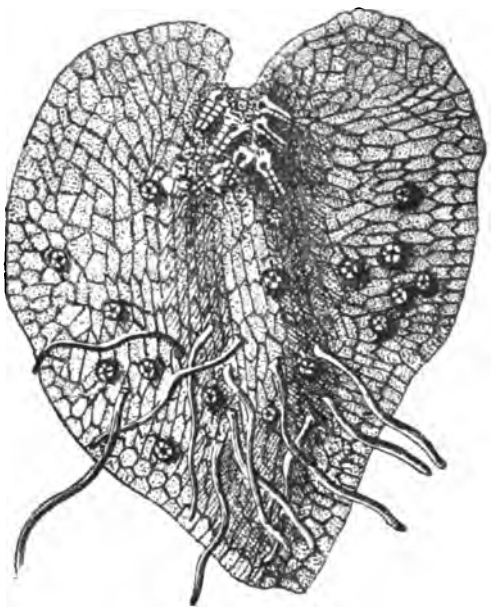

FIG. 4.—Under side of the prothallus of another fern, more magnified, showing the rhizoid radicles, the antherids dispersed over the surface, and the archegones clustered at the terminal notch.

complexity of their prothallus and simplicity of sporangia are accepted as indications of inferiority.

The relative perfection of the sporangium when taken

From the simplest type of sporangium, two lines of

Digitized by Google

increasing differentiation in the organ, or its support, can be traced—one leading to the Polypodiaceæ through the Cyatheæ, the other to Schizeaceæ, Gleicheniaceæ, and Marattiaceæ.

The earliest fern of which the fructification is known is the Devonian Palæopteris, Schimper. Its fructification consists of aborted leaflets supporting groups of oblong, stalked sporangia opening into two valves and disposed in threes on pedicles. Rhacopteris, of the same age, and perhaps not generically differing, has fructification which unites in a higher degree the characteristics of Osmunda and Botrychium, and giving birth probably to the Botryopteridæ of the later Carboniferous flora. Another genus, Sefftenbergia, is allied by the structure of its sporangium to Angiopteris (Marattiaceæ), though each sporangium is as yet isolated. The Palæozoic ferns did not at this period essentially differ from Osmunda and Todea.

The earliest example of definite grouping in the

FIG. 1.—1, magnified pinnule of one of the Lygodieæ of the genus Molopteris, showing the arrangement of the sporangia on the under side of the frond; 2, sporangium of the same, showing the group of apical cellules which disrupt the spore-case; 3, sorus of Gleichenia, showing the peripheral arrangement of the cellules which disrupt the spore-case; 4, sporangium before dehiscence.

sporangia is furnished by Oliogocarpia, in which three to five sporangia are inserted on a point near the ultimate terminations of the venules; but even here, though contiguous, they are distinct, and can be separated. In the later Carboniferous, Marattioid ferns for the first time occur with the sporangia united in a composite organ called a synangium, and soon after the Marattiaceæ reached their maximum development, and commenced, through forms now extinct, to differentiate towards the Gleicheniaceæ. The stages of development of the latter, and of the Schizeaceæ, are more difficult to trace, though both are represented in the Palæozoics by Howlea and Sefftenbergia respectively. The actual genus Gleichenia does not appear until the inferior Oolite, and Lygodium until the Cretaceous.

The Cyatheæ are represented in the Carboniferous by Thyrsopteris and in the Jurassic by Dicksonia, while true Polypodieæ cannot be traced farther back than the

spikes, and either contain two to eight macrospores, or small and very numerous microspores. In the germination of these spores the approach towards Gymnosperms becomes exceedingly apparent, and is consequently dwelt on at some length, the researches of Sachs, Luersen, and others being largely referred to. An even higher stage was in all probability reached in the Lepidodendrons, the vigorous and splendid growth of which formed the culminating development of the Lycopodiaceæ. The mathematical regularity of their growth, even in the most minute internal structure, is very striking. They formed large trees with acicular or falcate, perhaps deciduous leaves, and bore cones in pairs at the extremities of certain branches, differing exteriorily but little from those of Gymnosperms. The expanded bases of the scales or bracts bore the sporangia, those containing the macrospores being nearest the base. The stem comprised several layers, the centre being of pith formed of elongated prismatic cells. The next layer was woody, and gave off simple vascular threads to each leaflet, these penetrating obliquely the succeeding region of parenchyma and the cortical layers. The bark increases in density towards the exterior, and in some species the interior pith is absorbed in the woody layer.

Lepidodendron, with the greater part of the Palæozoic flora, became extinct during the Permian, leaving as representative the humble Isoëtes. This, however, is not necessarily a degraded type, and may have existed since Palæozoic times, though only known fossil in the later Eocenes, where it in no way differs from existing forms.

The Rhizocarps are beyond doubt the highest existing form of Cryptogam, but though in many respects so nearly approaching to Phanerogams, they are not, as we see them now, in the absolutely direct line of evolution. In all, the sporangia are protected by an enveloping altered leaf, or segment of a leaf, forming a fruit called a sporocarp, which in most cases attains a high degree of complexity. The entire group is aquatic, and stands in the same position towards fossil Rhizocarps that Isoëtes does to the Lepidodendrons. The Carboniferous Sphenophyllum has been shown to correspond to Salvinia, and the Rhætic

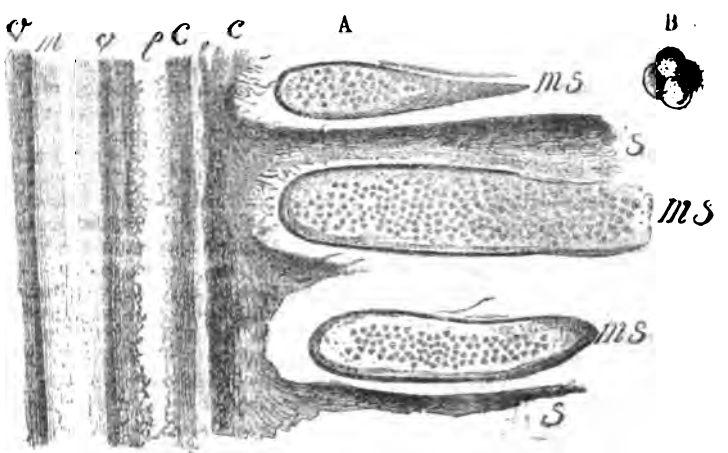

FIG. 10.—Reproductive organs of Lepidodendron with microsporangia and microspores. A, longitudinal section through upper part of sporangiocarp of Lepidostrobus (probably *L. Brownii*, Schimp), from the neighbourhood of Pézenas (Hérault); M, the central medullary region formed of parenchyma with elongated prismatic cells; V V, the woody layer of fibro-vascular region next the pith, showing large scalariform vessels; L, lacuna, in which delicate and partly disintegrated cells are studded; C C, cortical layer composed of a very dense outer and an inner layer, separated by a loose, nearly destroyed parenchyma; S, "sporangiospores," supporting very elongated micro-porangia filled, M S, with microspores aggregated in fours (these are slightly exaggerated in size); B, group of microspores magnified.

Sagenopteris to the Marsiliaceæ. Though the vegetative organs in the extinct forms attained far finer proportions and a higher and more delicate structure, the fructification, in Salvinia especially, appears the more complex. The existing genera have only been met with in the Eocene and Oligocene.

Thus while Angiosperms all present similarity in the reproductive process, Cryptogams preserve many of the stages by which the evolution of the higher forms has been accomplished. They also present every gradation in their vegetative organs, from the simplest and purely cellular plant to the equals of Phanerogams in point of structure. Except the Protophytes, all Cryptogams are impregnated by antherids, and present the antagonistic and alternate asexual and sexual generations, these being in fact their distinguishing characters. The authors' task

Digitized by Google

—to trace step by step the progressive stages by which the prothalloid phase has been diminished, and the ever, though gradually, increasing approach in the complexity and mode of reproduction to the Phanerogams—has demanded the most patient and prolonged research. The promised second volume will further diminish the hiatus still left between Phanerogams and Cryptogams, and make clear, the authors believe, the precise lines through which the evolution of the one from the other has been accomplished.

J. STARKIE GARDNER

MUSEUMS AND EXHIBITIONS IN JAPAN

THERE is probably no function of Government which the rulers of new Japan have performed so adequately and thoroughly, with such persistence and such unvarying success, as that which consists in the education of the people. It would be impossible in the space at our disposal to describe the course and results of education under the usurpation of the Shôgun; suffice it to say that, though learning of a peculiar kind always received support and encouragement, these were given on no sound or general system. The masses were neglected as beneath consideration, while literary labour of the best kind was always rewarded. No Japanese Horace need ever have lacked a generous Mecænas. But it was not until the restoration of the Mikado and the overthrow of the feudal organisation that a system of universal education which should reach the lowest classes of the people was introduced, and the Government of Japan then looked abroad to those Western lands, to which the eyes of all Japanese were then turned, for models on which to base their new scheme. American teachers of eminence were first brought to the new University established in Tokio; these were soon followed by subordinate instructors for the various schools in the local centres, and in six years after the restoration there were two large educational establishments—the University and the College of Engineering—besides numerous smaller ones in the capital, while every administrative division had its central school—all provided with competent foreign professors or teachers. A large normal college in Tokio trained instructors for the schools in the interior in Western knowledge and Western methods of teaching; and from that time to the present the wise and beneficent system of general education adopted by the Government has gone on extending itself into the remotest parts of the country. As mentioned in a previous article, the number of foreign instructors was gradually reduced, first in the interior, afterwards at the capital, as Japanese trained at home or abroad became competent to take their places. The history of this remarkable spread of education in Japan will be found in the annual reports of the Minister of Education to the Emperor, and in an excellent series of papers published by the Japanese Commissioners to the Philadelphia Exhibition. The spirit in which this work is carried out is well shown in a circular recently issued by the Minister of Education for the guidance of teachers in elementary schools. According to the *Japan Mail* this document contains sixteen clauses, embodying a number of directions for the conduct of school officials. The chief points are (1) "the importance of imparting a sound moral education to the students, both by precept and example, since the condition of a man's heart is of far greater moment than the extent of his knowledge; (2) the necessity of proper hygienic arrangements, which have more effect upon the health of the students than gymnastics or any other physical training; and (3) the value of mental energy in a teacher, for without it he cannot possibly support the fatigue and trouble of really careful tuition." The circular goes on to advise teachers not to constitute themselves advocates of any particular religious or political doctrines, and to take every opportunity of

their own stock of knowledge.[1]

But while thus caring for the education of the country, that of its risen generation has neglected. Besides annual and triennial exhibitions, museums have been established in large towns in the country, and it is to these we particularly refer in the present article. It remarked at the outset that the Japanese are sightseers; not the vulgar, pushing, noisy m we are too much accustomed in this country, orderly, pleased, and pleasing crowd. They anxious to see something new; failing this, th tent with their own temples and ancient rem visit to any of the numerous museums of T Sunday or other holiday, the stranger from cannot fail to be struck with the order, good h never-failing interest manifested by the pe descriptions of the objects are generally ver clear, so as to bring them within the meanest c sion; and when these are read out to a group one more learned than the rest, the exclamatio der, admiration, or delight are incessant, an pleasing contrast to languid or imperfect en quently taken by our own crowds in their mus

The first museum in Japan—the *Hakubutsu* was opened, as an experiment, in 1873. A few Western manufacture and some Japanese pr were placed in the Confucian Temple, situated the prettiest suburbs of Tokio. Vast crowds, chiefly no doubt by the foreign exhibits, visited daily; and the Government, acting, we believe advice of the governor of the city, determined t the exhibition considerably and make it perma was accordingly removed to a more central pos partially-dismantled residence of one of the d being chosen for this purpose. Here the collec deposited and gradually increased, until at the time it fills a range of narrow buildings nearly a of a mile in length. This may be called the pe museum of the capital. A visit to it would st accustomed to the museums of Europe with a sense of incongruity. Close to the lacquered carts and chairs of the emperors of a thousand y we find English machinery of yesterday; in o partment we see art treasures of a remote antiq the next, Minton and Wedgwood; a corridor co a large and valuable collection of the old paper brings us, it may be, to a collection of modern gl This jogging together of the ancient and modern, of familiar in the homes in the West with the precio rarities of the East; of the products of the sk loving care of old Japanese artists with, we may say, Brummagem, jars unpleasantly on foreign ta it must be remembered that this establishment is ha not for the educated foreigner or even native, but f Japanese shopkeeper, farmer, artisan, and lab whose interest is not a whit diminished when he f from a beautiful antique relic to a Bradford imm copy of the Milton shield. Indeed, we are not sur

[1] As an instance of the general spread of elementary instruct present writer may take this opportunity of mentioning what he saw an examination of some of the principal Japanese prisons in the neig autumn of last year. He found all the children and youths in so some cases numbering a few hundreds—attending the prison school or six hours each day, while the adults attended in the evenings Sundays. He saw in the chief penal settlement in Tokei seve hundred boys learning reading, writing, and the simple rules of arit In the senior class the boys were learning ciphering *mold Europea* from one of their own number. m very early times ; but it is
vernment have provided large
reign works for students. One
was founded in 1873, contained
f Chinese and Japanese works,
Dutch, and about 2000 volumes
in other European languages. It possesses a large reading-room, provided with many leading foreign journals ; admission is wholly free, and permission to borrow books for a certain period is easily obtained. The number of readers is about three thousand a month. Another, containing about 143,000 volumes, including many ancient books and manuscripts, is practically free, an entrance fee of less than a halfpenny being charged. In addition to these many of the leading towns throughout the country are provided with free libraries, which are much used and appreciated by students. The cost of foreign books renders these institutions peculiarly valuable to natives, who, as a rule, cannot afford to pay our heavy prices.

It will thus be seen that the introduction of museums and similar establishments was a happy move on the part of the Japanese Government ; they are heartily appreciated by the people, and their educating influence is immense. With the exception of the newspaper press no Western institution has been so rapidly or so successfully acclimatised in Japan.

THE INTERNATIONAL EXHIBITION AND CONGRESS OF ELECTRICITY AT PARIS[1]

III.

THE Congress held its concluding sitting on Wednesday, the 5th inst., and was formally dissolved. Three international Commissions are to be appointed in accordance with the recommendations of the Congress, viz. :—

1. A Commission to determine what length of mercury at zero Centigrade, with a section of a square millimetre, has a resistance equal to the theoretical Ohm, that is, to 10^9 C.G.S. units.

2. A Commission for the following distinct purposes :—To arrange for a general system of observations of atmospheric electricity ; to arrange for a general system of observations on earth-currents ; to determine the best system of lightning-conductors ; to investigate the practicability of a general system of automatic transmission by telegraphic wires of the indications of meteorological instruments. The idea of this last investigation is taken from the apparatus of M. van Rysselbergh, which we described in a previous notice. In fact it is understood that the Committee will report on the advisability of extending to Europe generally the system which already exists in Belgium.

3. An International Commission for fixing upon a standard of luminous intensity, to be used in measurements of electric lights, and for deciding upon the best methods of making such measurements.

The following recommendations have also been made by the Congress :—That the diameters of wires employed in telegraphy be stated in millimetres ; that the cultivation of the gutta-percha tree be guarded by suitable regulations, to prevent this important product from becoming scarce ; that the Governments of the different countries be requested to legislate on the subject of submarine cables, the present state of the law being insufficient to guarantee the rights of property in such cables.

In illustration of the present state of things Dr. C. W. Siemens mentioned a case where a cable which his firm had laid was wilfully cut by a captain who had caught it with his anchor in deep water, and the law afforded no remedy. It is also understood that regulations are to be made as to the repair of cables which are crossed by other cables belonging to a different company.

A further recommendation, that all countries should adopt for ships engaged in laying cables the same code of signals which is already in use in English ships was withdrawn upon the presentation of indubitable evidence that the code in question was adopted months ago in a note signed by the representatives of all the nations concerned.

[1] Continued from p. 533.

Digitized by Google

All the proceedings of the Congress have been conducted in French, and it was a novel sensation to most of us to see our English friends mount the tribune and deliver their sentiments in French; a still more novel sensation to those who for the first time ventured upon such an undertaking themselves. You first rise in your place and say, *Je demande la parole*, at the same time holding up your hand to catch the eye of the president. On his replying, *Vous avez la parole*, you walk from your place to the tribune, which is a raised platform in front of the audience, and there, with the eyes of the assembled *savans* of Europe fixed upon you, you must carry out your rash undertaking, with all your imperfections on your head. It is like the sensation of diving for the first time into deep water, where you must swim or drown.

In these international gatherings very wide deviations from the correct standards of grammar and pronunciation are indulgently tolerated, and the English have certainly not appeared to disadvantage as compared with the Germans; though it has been by no means a rare occurrence to see a speaker of either of these nations in sore straits for want of a word. There is one great advantage in conducting a Congress in a foreign tongue, and that is that the difficulty of the situation puts a wholesome check upon any tendency to verbiage on the part of a speaker; he is glad to express his meaning in the simplest manner that he can, and to desist as soon as his laborious task is accomplished; but this advantage is to some extent lost where, as on the present occasion, the language is the native tongue of half the members of the Congress. Some of the later sittings were decidedly dull and unprofitable, being mainly occupied with prolix dissertations of no general interest. The *Salle des Séances*, with its draped walls and high canvas roof, is very stifling to the voice, and much of what was said was insufficiently heard by the bulk of the audience.

The official reports of the proceedings were taken not by shorthand writers, but by young men skilled in science, who wrote abstracts of the speeches in longhand during their delivery; and it must be acknowledged that they did their work exceedingly well. The report thus taken of each meeting was printed and laid before the members at the next meeting, to be adopted before proceeding to any other business. It is called the *procès verbal*, and is treated like the minutes of an English meeting, but it is much fuller than our minutes usually are.

So much of these reports as relates to the discussions on units has been reprinted in the *Révue Scientifique*, No. 13. We have not observed reprints of any other discussions of the Congress.

The jury are now hard at work. They have divided themselves into six groups, which are subdivided into fourteen classes according to the first fourteen classes of the catalogue; and some of the more important of these classes have been still further subdivided; the total number of jurors being about 150, one-half of whom are French. By the help of this division of labour the official inspections of the exhibits have been, we believe, completed; but some days will be devoted to carrying out a series of experimental tests, which have already been commenced; and it is probable that some valuable data relative to electric lights and the machines which furnish their electricity will remain as one definite result of the present Exhibition.

In connection with these experiments a good story is told respecting resistance-coils. An eminent firm sent off several patterns of resistance-boxes to the Exhibition, but being out of one of their favourite types, they supplied its place by an empty box having exactly the outward appearance of the genuine article. As ill-luck would have it, the jury selected this particular box as being precisely what they wanted to assist them in their experiments, and asked for the loan of it. The representative on the spot, being ignorant of the above, and appreciating the compliment paid to box with the utmost alacrity. The re imagined than described. Applicatio another eminent firm for a box whic spicuous position in their case of exh turned out to be a dummy, *but the jo* so far this time, as the representative declared the fact.

recent Social Science meeting at Darwin to Mrs. Emily Talbot, in the investigation of the mental infants. He specifies points of possess some scientific interest, arents, for instance, influence the en at any age, either at a very ced stage? This could perhaps mistresses, if a large number of cording to age and their mental accordance with the education of uld be discovered. As observa- ties developed in young children, bly be exercised in an equal degree nd uneducated persons, it seems itted effect from education would hat advanced age. It would be a similar manner, the truth of the coloured children at first learn as t that they afterwards fall off in d that education acts not only on sion on the race, this would be a king on this all-important sub- ldren sometimes exhibit at a very es, for which no cause can be assigned, although occasionally they may be accounted for by reversion to the taste or occupation of some progenitor; and it would be interesting to learn how far such early tastes are persistent and influence the future career of the individual. In some instances such tastes die away without apparently leaving any after effect; but it would be desirable to know how far this is commonly the case, as we should then know whether it were important to direct, as far as this is possible, the early tastes of our children. It may be more beneficial that a child should follow energetically some pursuit, of however trifling a nature, and thus acquire perseverance, than that he should be turned from it, because of no future advantage to him. I will mention one other small point of inquiry in relation to very young children, which may possibly prove important with respect to the origin of language, but it could be investigated only by persons possessing an accurate musical ear: children, even before they can articulate, express some of their feelings and desires by notes uttered in different notes. For instance, they make an interrogative noise, and others of assent and dissent in different tones, and it would, I think, be worth while to ascertain whether there is any uniformity in different children in the pitch of their voices under various frames of mind."

In a letter to the *Madras Mail* of September 8 on the use of gigantic sea-weed as a protective agent for shores, Capt. J. M. Taylor, the Master-Superintendent of Madras, gives the following interesting "sea-serpent" story:—"A notable incident connected with this sea-weed, is recalled to my recollection, by Dr. Farnell's letter. About fifteen years ago, while I was in my ship at anchor in Table Bay, an enormous monster, as it appeared, was seen drifting, or advancing itself round Green Point, into the Harbour. It was more than one hundred feet in length, and moved with an undulating snake-like motion. Its head was crowned with what appeared to be long hair, and the keen-sighted among the affrighted observers declared they could see its eyes and distinguish its features. The military were called out, and a brisk fire poured into it at a distance of about five hundred yards. It was hit several times, and portions of it knocked off. So serious were its evident injuries, that on its rounding the point it became quite still, and boats went off to examine it and complete its destruction. It was found to be a specimen of the sea-weed above mentioned, and its stillness after the grievous injuries inflicted was due to its having left the ground swell and entered the quiet waters of the Bay."

Dr. B. W. Richardson is about to continue the series of lectures delivered by him in the spring at the instance of the "Ladies' Sanitary Association," of Berners Street. The lectures are devoted generally to the subject of "Domestic Sanitation." In the forthcoming series, which will be commenced in the Lower Hall, Exeter Hall, on Saturday, the 22nd inst., the structure and functions of the nervous system, and the physical and mental training of the young, will occupy a prominent place.

The Phylloxera Congress, to which we have already referred, was opened on Sunday at Bordeaux.

The Rev. J. Hoskyns-Abrahall writes to the *Times* from Combe, near Woodstock, October 3:—"On October 1, about 8.42 p.m., when I was walking in a north-westerly direction, about three hundred yards north-west of Hanborough Station, which is three-quarters of a mile north-west of Oxford, the eastern sky was suddenly flooded with a light that vied with that of the moon, which shone more than half full in the west. Turning round, I beheld a magnificent meteor, of a pale yellow hue, descending with a slow motion, vertically. It seemed larger than Jupiter. When I first saw it, it had dropped about a third of the distance from the zenith to the horizon; after traversing another third of that space it burst without scattering any sparks."

THE Exhibition of the Photographic Society is now open at the rooms of the Old Water-Colour Society in Pall Mall.

A NEW form of compressed air locomotive engine, the invention of a Mr. Hardie, has been put to a practical, and, it is said, successful test in New York, on the Second Avenue elevated railroad. The compressed air is stored in four tubular tanks connected with each other by pipes so as virtually to form one large reservoir. It is said that a saving of 50 per cent. is effected on the cost of working a locomotive by the use of the new invention.

A TELEGRAM from Geneva last Thursday states that another large rift has opened in the Tschingel, a circumstance which indicates that the mountain is still in movement. The inhabitants of Elm, many of whom had returned, have been again warned to leave their houses.

WE have received a very interesting coloured picture of the moon, reproduced from a telescopic painting by Mr. Henry Harrison of New York. It is the first of a series, and represents the moon at the stage of the three days crescent. The picture is twenty-four inches square, with the moon eighteen inches in diameter, and the execution is excellent. It shows the earth-shine very distinctly on the surface in shadow. As to its accuracy, we notice from a letter by Prof. Harkness that it was tested at the United States Naval Observatory, and the result is stated to have been all that could be desired. This picture is to be followed up by five others representing the moon at various succeeding stages. The London agent for the picture is Mr. William Wesley.

THE June number of the *Journal* of the Straits Branch of the Royal Asiatic Society, published half-yearly (London: Trübner and Co.) contains several useful articles:—Some account of the mining districts of Lower Perak, by J. Errington de la Croix; The Folklore of the Malays, by W. E. Maxwell; Notes on the Rainfall of Singapore, by J. J. L. Wheatley; Journal of a voyage through the Straits of Malacca on an expedition to the Moluccs Islands, by Capt. Walter Caulfield Lennox; a sketch of the career of James Richardson Logan, by J. Turnbull Thomas; and a memorandum on the various tribes inhabiting Penang and Province Wellesley, by J. R. Logan. A journal with such a programme deserves every encouragement, and we hope it will receive it.

THE Society for Promoting Christian Knowledge has issued a series of coloured zoological diagrams representing various typical specimens of animal life, from corals and anemones to mammals. They are accurately and nicely executed after Leutemann's Zoological Atlas for Schools. Why should we still have to go to Germany for such productions?

UNDER the title of "Anglo-Saxon Britain" Mr. Grant Allen has published (through the S.P.C.K.) an interesting little volume on the early history of England. He has taken pains to master all the results of recent research in archæology and ethnology, and therefore the book has a more scientific flavour than usual with such works. While adopting generally the views associated with the names of Freeman and Green, he shows independence of view, and treats his subject in an unusually unconventional manner. Either as a reading-book or as a text-book for the special period, it ought to be useful; it is certainly interesting.

IN "Miscellanies of Animal Life," by Elizabeth Spooner (S.P.C.K.), the authoress has brought together a number of interesting and instructive extracts from various good authorities as to the habits of animals, which ought to prove interesting to children.

CAPT. POPELIN, of the Belgian station at Karema, Lake Tanganyika, whose death was lately announced, appears to have died when on his way from Ujiji to the Mampara district, in Southern Ugulu.

ON SOME APPLICATIONS OF ELECTRIC ENERGY TO HORTICULTURE AND AGRICULTURE[1]

ON the 1st of March, 1880, I communicated to the Royal Society a paper "On the Influence of Electric Light upon Vegetation, &c.," in which I arrived at the conclusion that electric light was capable of producing upon plants effects comparable to those of solar radiation; that chlorophyll was produced by it, and that bloom and fruit, rich in aroma and colour, could be developed by its aid. My experiments also went to prove that plants do not as a rule require a period of rest during the twenty-four hours of the day, but make increased and vigorous progress if subjected (in winter time) to solar light during the day and to electric light during the night.

During the whole of last winter I continued my experiments on an enlarged scale, and it is my present purpose to give a short account of these experiments, and of some further applications of electric energy to farming operations (including the pumping of water, the sawing of timber, and chaff and root-cutting) at various distances, not exceeding half a mile from the source of power, giving useful employment during the daytime to the power-producing machinery, and thus reducing indirectly the cost of the light during the night-time.

The arrangement consists of a high-pressure steam-engine of 6 horse-power nominal, supplied by Messrs. Tangye Brothers, which gives motion to two dynamo-machines (Siemens D), connected separately to two electric lamps, each capable of emitting a light of about 5000 candle-power. One of these lamps was placed inside a glass house of 2318 cubic feet capacity, and the other was suspended at a height of 12 to 14 feet over some sunk greenhouses. The waste steam of the engine was condensed in a heater, whence the greenhouses take their circulating supply of hot water, thus saving the fuel that would otherwise be required to heat the stoves.

The experiments were commenced on October 23, 1880, and were continued till May 7, 1881. The general plan of operation consisted in lighting the electric lights, at first at 6 o'clock, and during the short days at 5 o'clock every evening except Sunday, continuing their action until dawn.

The outside light was protected by a clear glass lantern, whilst the light inside the house was left naked in the earlier experiments, one of my objects being to ascertain the relative effect of the light under these two conditions. The inside light was placed at one side over the entrance into the house, in front of a metallic reflector, to save the rays that would otherwise be lost to the plants within the house.

The house was planted in the first place with peas, French beans, wheat, barley, and oats, as well as with cauliflowers, strawberries, raspberries, peaches, tomatoes, vines, and a variety of flowering plants, including roses, rhododendrons, and azaleas. All these plants being of a comparatively hardy character, the temperature in this house was maintained as nearly as possible a 60° Fahr.

The early effects observed were anything but satisfactory While under the influence of the light suspended in the open air over the sunk houses the beneficial effects due to the electric light, observed during the previous winter, repeated themselves, the plants in the house with the naked electric light soon manifested a withered appearance. Was this result the effect of the naked light, or was it the effect of the chemical products—nitrogenous compounds and carbonic acid—which are produced in the electric arc?

Proceeding on the first named assumption, and with a view of softening the ray of the electric arc, small jets of steam were introduced into the house through tubes, drawing in atmospheric air with the steam, and producing the effect of clouds interposing themselves in an irregular fashion between the light and the plants. This treatment was decidedly beneficial to the plants, although care had to be taken not to increase the amount of moisture thus intro-

[1] Paper read at the British Association by C. William Siemens, D.C.L. LL.D., F.R.S., M. Inst. C.E.

Digitized by Google

duced beyond certain limits. As regards the chemical products it was thought that these would prove rather beneficial than otherwise, in furnishing the very ingredients upon which plant-life depends, and further that the constant supply of pure carbonic acid resulting from the gradual combustion of the carbon electrodes might render a diminution in the supply of fresh air possible, and thus lead to economy of fuel. The plants did not, however, take kindly to these innovations in their mode of life, and it was found necessary to put a lantern of clear glass round the light, for the double purpose of discharging the chemical products of the arc, and of interposing an effectual screen between the arc and the plants under its influence.

The effect of interposing a mere thin sheet of clear glass between the plants and the source of electric light was most striking. On placing such a sheet of clear glass so as to intercept the rays of the electric light from a portion only of a plant, for instance a tomato plant, it was observed that in the course of a single night the line of demarcation was most distinctly shown upon the leaves. The portion of the plant under the direct influence of the naked electric light, though at a distance from it of nine to ten feet, was distinctly shrivelled, whereas that portion under cover of the clear glass continued to show a healthy appearance, and this line of demarcation was distinctly visible on individual leaves. Not only the leaves, but the young stems of the plants soon showed signs of destruction when exposed to the naked electric light, and these destructive influences were perceptible, though in a less marked degree, at a distance of twenty feet from the source of light. A question here presents itself that can hardly fail to excite the interest of the physiological botanist. The clear glass does not apparently intercept any of the luminous rays, which cannot therefore be the cause of the destructive action. Prof. Stokes showed, however, in 1853, that the electric arc is particularly rich in highly refrangible invisible rays, and that these are largely absorbed in their passage through clear glass; it therefore appears reasonable to suppose that it is those highly refrangible rays beyond the visible spectrum that work destruction on vegetable cells, thus contrasting with the luminous rays of less refrangibility, which, on the contrary, stimulate their organic action.

Being desirous to follow up this inquiry a little further, I sowed a portion of the ground in the experimental conservatory with mustard and other quick-growing seeds, and divided the field into equal radial portions by means of a framework, excluding diffused light, but admitting light at equal distances from the electric arc. The first section was under the action of the naked light, the second was covered with a pane of clear glass, the third with yellow glass, the fourth with red, and the fifth with blue glass. The relative progress of the plants was noted from day to day, and the differences of effect upon the development of the plants was sufficiently striking to justify the following conclusions: — Under the clear glass the largest amount of and most vigorous growth was induced; the yellow glass came next in order, but the plants, though nearly equal in size, were greatly inferior in colour and thickness of stem to those under the clear glass; the red glass gives rise to lanky growth and yellowish leaf, while the blue glass produces still more lanky growth and sickly leaf. The uncovered compartment showed a stunted growth with a very dark and partly shrivelled leaf. It should be observed that the electric light was kept on from five p.m. till six a.m. every night except Sundays during the experiment, which took place in January, 1881, but that diffused daylight was not excluded during the intervals; also that circulation of air through the dividing framework was provided for.

These results are confirmatory of those obtained by Dr. J. W. Draper[1] in his valuable researches on plant cultivation in the solar spectrum in 1843, which led him to the conclusion, in opposition to the then prevailing opinion, that the yellow ray, and not the violet ray, was most efficacious in promoting the decomposition of carbonic acid in the vegetable cell.

Having, in consequence of these preliminary inquiries, determined to surround the electric arc with a clear glass lantern, more satisfactory results were soon observable. Thus, peas which had been sown at the end of October produced a harvest of ripe fruit on February 16, under the influence, with the exception of Sunday nights, of continuous light. Raspberry stalks put into the house on December 16 produced ripe fruit on March 1, and strawberry plants put in about the same time produced ripe fruit of excellent flavour and colour on February 1. Vines which broke on December 26 produced ripe grapes of stronger flavour than usual on March 10. Wheat, barley, and oats shot up with extraordinary rapidity under the influence of continuous light, but did not arrive at maturity; their growth having been too rapid for their strength, caused them to fall to the ground, after having attained the height of about twelve inches.

Seeds of wheat, barley, and oats, planted in the open air and grown under the influence of the external electric light, produced, however, more satisfactory results; having been sown in rows on January 6, they germinated with difficulty, on account of frost and snow on the ground, but developed rapidly when milder weather set in, and showed ripe grain by the end of June, having been aided in their growth by the electric light until the beginning of May.

Doubts have been expressed by some botanists whether plants grown and brought to maturity under the influence of continuous light would produce fruit capable of reproduction, and in order to test this question the peas gathered on February 16 from the plants which had been grown under almost continuous light action were replanted on February 18. They vegetated in a few days, showing every appearance of healthy growth.

Further evidence on the same question will be obtained by Dr. Gilbert, F.R.S., who has undertaken to experiment upon the wheat, barley, and oats grown as above stated; but still more evidence will probably be required before all doubt on the subject can be allayed.

I am aware that the great weight of the opinion of Dr. Darwin goes in favour of the view that many plants, if not all of them, require diurnal rest for their normal development. In his great work on "The Movements of Plants" he deals in reality with plant life, as it exists under the alternating influence of sunlight and darkness; he investigates with astonishing precision and minuteness their natural movements of circumnutation or nightly or nyctitropic action, but does not extend his inquiries to the conditions resulting from continuous light. He even proves that nyctitropic action is instituted to protect the delicate leaf-cells of plants from refrigeration by radiation into space, but it does not follow, I would submit, that this protective power involves the necessity of the hurtful influence. May it not rather be inferred from Dr. Darwin's investigations that the absence of light during night-time involved a difficulty to plant life that had to be met by special motor organs, which in time would perhaps be gradually dispensed with by plants if exposed to continual light for some years or generations?

It is with great diffidence, and without wishing to generalise, that I feel bound to state as the result of all my experiments, extending now over two winters, that although periodic darkness evidently favours growth in the sense of elongating the stalks of plants, the continuous stimulus of light appears favourable for healthy development at a greatly accelerated pace, through all the stages of the annual life of the plant, from the early leaf to the ripened fruit. The latter is superior in size, in aroma, and in colour to that produced by alternating light, and the resulting seeds are not at any rate devoid of regerminating power.

Further experiments are necessary, I am aware, before it would be safe to generalise, nor does this question of diurnal rest in any way bear upon that of annual or winter rest, which probably most plants, that are not so-called annuals, do require.

The beneficial influence of the electric light has been very manifest upon a banana palm, which at two periods of its existence, viz., during its early growth and at the time of its fruit development, was placed (in February and March of 1881 and 1881) under the night action of one of the electric lights set behind glass at a distance not exceeding two yards from the plant; the result was a bunch of fruit weighing 75 pounds, each banana being of unusual size, and pronounced by competent judges to be unsurpassed in flavour. Melons also, remarkable for size and aromatic flavour, have been produced under the influence of continuous light in the early spring of 1880 and 1881, and I am confident that still better results may be reached when the best conditions of temperature and of proximity to the electric light have been thoroughly investigated.

My object hitherto has rather been to ascertain the general conditions necessary to promote growth by the aid of electric light than the production of quantitative results; but I am disposed to think that the time is not far distant when the electric light will be found a valuable adjunct to the means at the disposal of the horticulturist, in making him really master

filled with water may be taken at 15 cwt. per horse-power. Moreover, the portable engine requires a continuous supply of water and fuel, and involves skilled labour in the field, whilst the electrical engine receives its food through the wire (or a light rail upon which it may be made to move about) from the central station, where power can be produced at a cheaper rate of expenditure for fuel and labour than in the field. The use of secondary batteries may also be resorted to with advantage to store electrical energy when it cannot be utilised.

In thus accomplishing the work of a farm from a central-power station, considerable savings of plant and labour may be effected; the engine-power will be chiefly required for day work, and its night work for the purposes of electro-horticulture will be a secondary utilisation of the establishment, involving little extra expense. At the same time the means are provided of lighting the hall and shrubberies in the most perfect manner, and of producing effects in landscape gardening that are strikingly beautiful.

THE ELECTRICAL DISCHARGE, ITS FORMS AND ITS FUNCTIONS[1]

II.

AMONG the various circumstances which combine to determine the character of the discharge, one of the most important is the size of the negative terminal. And in this respect, as well as in others, the negative differs fundamentally from the positive. If the negative be small, not so much in comparison with the positive as in absolute magnitude, and perhaps also in reference to the diameter of the tube, the tube will offer great "resistance," as it is termed, to the passage of the discharge. On the other hand, if the negative be large, the discharge passes with comparative ease. In the first case, even when the discharge passes, striæ are formed only with difficulty, if at all; in the second they are readily formed. This may easily be shown by using a tube with one small and one large terminal, which can be used alternately as positive and as negative; or by a tube having a negative terminal of variable length.

The same dependence of striation upon the size of the negative may be shown in the case of a tube with a negative terminal of barely sufficient size. In this case, if the tube be touched by the hand (an operation which, as will be hereafter explained, is equivalent to enlarging the negative), striæ will be brought out clear and distinct, while without this assistance they appear only in a confused and irregular manner.

Other characteristic features of the negative terminal would deserve our attention if time permitted. Thus, the well-known phenomena of the so-called "Holtz tube" (or tube divided into compartments by diaphragms furnished with narrow pipes leading from one compartment to the next, and all pointed in one direction), show that a small aperture will serve as a negative, but not as a positive terminal. This property has been generalised by Goldstein, who, using as a negative terminal a cylinder of non-conducting substance pierced with fine holes, reproduces all the phenomena appertaining to an ordinary metallic negative.

And, even apart from the phenomena of vacuum tubes, it would not be difficult to adduce instances showing the importance of the size of the negative terminal in electrical discharges generally. Of these I will now mention only the latest. In making some modifications of Planté's battery M. de Pozzer has found that, if the negative electrode be made of a plate of lead of half a millimetre in thickness, and the positive of one of two-thirds of a millimetre, but the former double the size of the latter, great advantage arises from the greater size of the negative. The discharge from a battery having a negative double as large as the positive lasted, on an average of several experiments, for an hour; while that from a battery, in which the sizes of the electrode were reversed, lasted only half an hour. The effect of a battery with electrodes of equal size appears to have been intermediate to that of the two others.

From these phenomena, and especially from those of the moving terminal, as well as from other considerations, it appears that the general configuration of the discharge is mainly determined at the negative terminal.

In order, however, to experiment with any hope of progress

[1] A Lecture delivered before the British Association at York on September 8, 1881, by William Spottiswoode, D.C.L., LL.D., President of the Royal Society. Continued from p. 551.

in our knowledge of the nature and *modus operandi* of the discharge, we ought to be in a position to modify the discharge, so as to compare it under different circumstances. The methods hitherto usually employed for this object have been an alteration in the gas used, an alteration of the pressure, and a diversity of figure in the tube or in its terminals. Of the general character of the changes due to such alterations we have already seen something. But, besides these alterations, which are of a structural or instrumental character, it is also desirable to operate on a discharge actually *in transitu*. One of the methods, in fact the only one, employed until lately is that of the magnet, which was used as long ago as the time of Grove, Plücker, and other early experimenters. It is well known that a magnet will displace a movable conductor when carrying a current, according to laws established by Ampère. The same is true, in general terms, with respect to a discharge traversing an exhausted tube.

Thus, in the tube now before you, you will see that when one pole of a magnet is presented to the tube, the discharge is thrown to one side of the tube; and when the other pole is so presented the discharge is thrown to the other side. These two main features, however, very inadequately describe the actions of a magnet, which in fact operates separately not only upon each stria as a unit, but even upon the various parts of a stria in such a way as to deform it as well as to displace it. But they involve the main characteristics of the magnetic action, and must suffice on the present occasion to show that in the magnet we have a powerful instrument for examining the properties and functions of the discharge, even (if the term may be permitted) in the living specimen.

The other principal mode of operating on the discharge consists in reducing it to what has been called the "sensitive state"; *i.e.* to a state in which the position of the luminosity is affected by the approach of a conductor to the tube. For the details of an experimental investigation into the phenomena of this state, and a discussion of the conclusions that may be drawn therefrom, the reader is referred to the *Philosophical Transactions* of 1879 and 1880. But the following remarks may serve to convey some notion of the method and its issues. Sensitiveness is produced by breaking the circuit with a short interval of air, or, as it is usually described, by interposing an "air-spark" in one branch of the circuit, viz. either that leading from the positive, or in that leading from the negative, terminal of the machine to the tube, or by otherwise rendering the discharge intermittent. The effect of this is to discharge the electricity discontinuously, so that from time to time there passes into the tube a comparatively large quantity of electricity at a higher tension than would otherwise be the case. By this means the gas in the interior of the tube, or perhaps the interior surface of the tube itself, becomes momentarily charged with electricity, thus creating an electric tension, which may be discharged or "relieved" by a displacement in the electricity on a conductor brought near, or in contact with, the tube. This causes or permits a discharge from the interior of the tube itself of the electricity of an opposite kind to that with which the tube itself is charged. If the air spark is on the positive side the charge on the tube is positive, and the relief negative, and *vice versâ*. From this it follows, as might have been expected, that the effect of the relief on the visible discharge is different in the two cases. In each case the part of the inner surface of the tube nearest to the conductor acts as a *quasi* terminal. As a general rule, with a positive air-spark, the relief, being negative, tends to produce a dark space, and thereby gives the appearance of a repulsion of the luminous column. With a negative air-spark the relief, being positive, tends to produce a stria; it thereby causes luminosity, and gives an appearance of attraction of the luminous column.

The appearance of the luminous column when produced under the action of an air-spark is usually amorphous or unstratified, although this is not always the case. In the case of a positive air-spark the column is more or less constricted and confined to the central part of the tube; in the case of a negative air-spark it is more diffused, and usually fills the whole diameter of the tube. This is doubtless due to a gradual discharge from the sides of the tube, and is in accordance with what has been said above.

Under suitable circumstances this relief discharge may be made to bring out artificial striæ from an amorphous discharge, the position of the striæ depending upon the character of the air-spark used. The positions occupied by striæ in the one case will be occupied by dark spaces in the other, and *vice versâ*.

The facts here adduced, together with many others based upon a long series of experiments, all tend to the conclusion that, whatever the number or form of the striæ in a stratified column, each stria is to be regarded as a physical unit, and that in each unit we have represented all the elements of a complete discharge. The form of each stria is in every case determined by that of its immediate predecessor, reckoned from the negative end. This may be verified, among other ways, by observing the form of the successive striæ when distorted by the influence of a magnetic field. The same research has further established the fact that the negative glow and the haze behind it, which terminates in what is usually known as the negative dark space, is a stria turned as it were inside out by the influence, the shape and the character of the negative terminal. From the mode in which this stria is connected with the negative terminal it has been called the "anchored stria."

The relief effects, may, however, be produced equally well by connecting a point on the surface of the tube with the opposite, or non-air-spark terminal, instead of with earth. By this means we supply a charge of electricity of the opposite name to that with which the tube has been charged, and obtain a result of a similar character to that of ordinary relief.

Alongside of the relief effects above mentioned there is also a system of what we have termed "special effects," which latter are converse to the former, each to each. These are produced by connecting a point on the outside of the tube with the air-spark terminal itself. The special effect with a positive air-spark is equivalent to a relief effect with a negative air-spark, and *vice versâ*.

Lastly, all these effects may be produced by means of impulsive discharges to the outside of the tube from an independent source of electricity, such as a second Holtz machine. And, *mutatis mutandis*, the corresponding effects may be produced by this method even on a non-sensitive discharge. This completes the entire cycle of phenomena due to impulsive action *ab extra*.

The character of these effects being known once for all, the impulsive action may be used as a test of the nature of a discharge (*i.e.* whether positive or negative) passing through a given tube. For example, we may experimentally verify in the case of a coil discharge what might have been anticipated on the principles now established. Such a discharge is in fact equally intermittent from both ends. There is no reason why either terminal should be regarded as the air-spark terminal rather than the other. Hence we might expect that the discharge would be positive through about one-half of the tube, and negative through the remainder, with a neutral zone between them. And such proves to be the case. But more than this, if we attach a small condenser to either terminal of the tube, so as to tone down the impulsiveness of the discharge at that end, we can thereby alter the proportions of the positive and the negative parts of the discharge and shift the position of the neutral zone at will.

The distinctive character which it is thus possible to convey to the whole, or to the two parts of one and the same discharge, naturally leads us to examine whether it be not possible entirely to separate one from the other, and to produce what may be called a unipolar discharge. And this in fact may be done, by connecting the one terminal of the tube through an air-spark in one branch of the circuit, and by leaving the other disconnected, we may produce a discharge which, having plunged blindly into the tube, and finding no response from the other end, returns upon itself, and finds exit by the way by which it came. The unipolar discharge is essentially intermittent, and therefore sensitive. The positive is conical in form and tapering towards its end: the negative is broad, and, so far as it extends, it fills the entire width of the tube. Lastly, two unipolar discharges of the same name can be produced in the same tube; they repel one another, and each returns like a single one.

From these experiments we conclude that the independence of the discharge from each terminal is so complete that we can cause will cause discharges from the two terminals to be equal in intensity but opposite in sign (as in the case of the coil) or of any degree of inequality (as in the case of the coil with a small condenser). Or we can cause the discharge to be from one terminal only, the other terminal acting merely receptively (as in the case of the air-spark discharge); or we can cause the discharge to pass from one terminal only and return to it by the other terminal not taking any part in the discharge; or, finally, we can make the two terminals pour forth independent discharges of the same name, each of which passes back through the terminal whence it came.

One of the most important consequences which follows from

Digitized by Google

these considerations is that the discharges at the two terminals of the tube are so far independent as to be primarily determined each by the conditions at its own terminal, and only in a secondary degree, if at all, by the conditions that exist at the opposite terminal. And since the discharges are not necessarily the same at both terminals, the tube must contain free charges at different times. A tube is therefore not like a conductor, but is an independent electrical system, holding much the same position as the air-vessel in a forcing-pump. All the electricity that goes into it goes out again, but this is true only when we consider the whole discharge from the beginning to the end, and it may not be true even approximately during a small finite time. This independence of the discharges from the two terminals in the passage of electricity through rarefied gases dissipates the error of seeking analogies in metallic conduction; and shows that any obedience to regular laws as to change of potential as we proceed along the tube, resistance, &c., must arise from the fact that the effects measured are really average effects over an interval of time very long compared with the duration of the individual discharges.

The importance which attaches to the negative end of the discharge has led experimenters to examine whether the features appertaining to it could not be still further enlarged. And the only thing requisite to carry the experiments to a limit was an instrumental method of improving the vacuum to the degree required. This was furnished by Mr. Crookes' refinements on the Sprengel pump. In a series of most remarkable experiments he has shown, as mentioned above, not only that the striated column may be reduced to zero, but that the anchored stria itself may be so driven back that the blank space in question may be made to occupy the entire length of the tube.

When an exhaustion such as that described, or an exhaustion nearly equal to it, has been reached, a phenomenon, previously noticed, but not before made the subject of serious inquiry, presents itself. Certain parts of the interior surface of the tube become luminous with phosphorescent light. The colour of this light depends on the nature of the glass, and not in any way on the nature of the residual gas within the tube, nor on the substance of which the terminal is made. With German glass the phosphorescent light is green, with English glass it is blue. But the portion of the glass thus rendered luminous depends upon the form and position of the negative terminal. This phenomenon is supposed to be due to the streams of gaseous particles shot off from the neighbourhood of the negative terminal during the discharge. Although there is reason to think that these streams are an accompaniment rather than an integral part of the discharge, yet the particles would seem to be themselves charged with electricity, inasmuch as their paths are affected by a magnet, just as is a movable conductor carrying a current, or a charged body in rapid motion.

The whole subject of these streams, their power of heating metals and other substances, the shadows cast by bodies interposed in their path, and other properties of them, have been so well and so fully illustrated by Mr. Crookes both in published memoirs and in a lecture before this Association, that it is unnecessary for me now to dwell upon the subject in detail.

Their nature and properties, however, having been thus in the main determined, these streams have proved a valuable auxiliary in an investigation of what have been called the 'small time-quantities" involved in the discharge. The discharge is, as has been already shown, a complex phenomenon, the various parts of which, although not entirely separable, may be shown to occupy different periods of time; and the length of these periods may be compared with one another, and with other known electrical phenomena. We cannot, it is true, make any absolute determinations of the time occupied in any of them, but we may still form a table of relative magnitudes of these small time-quantities. And I will now endeavour in a few words to give some idea of the nature of these quantities, and of the method whereby they have been measured.

If we take a tube of such high exhaustion as to cause the discharge to become intermittent, or if we use a positive air-spark of sufficient length with a tube of fair exhaustion, phosphorescent light, due to molecular streams, will be seen on the inner surface of the glass near the negative terminal. If then a patch of tinfoil, connected with earth, be placed on any other part of the tube, it will cause negative relief discharges to take place from the glass immediately within it, producing phosphorescence on the opposite side of the tube.

If any solid object, such as a piece of wire, should be present in the tube below the point of contact, it will cast a shadow on the phosphorescence, precisely as in Crookes' experiments with the streams from the negative terminal. If there be two points of relief contact, the same object will throw two shadows, in directions conformable with radiations from each. To these, other experiments might be added.

A determination of the precise directions in which these molecular streams issue from a relieving surface is not a very simple problem; and we must here content ourselves with showing that, in the case of intermittent discharges at least, the streams do not issue normally. If a strip of tinfoil placed along the tube be used as a relieving surface, the phosphorescence takes the form of a sheet wrapped round the tube; if the strip be wrapped round the tube, the phosphorescence takes the form of a sheet laid along the tube. If contact be made with the finger over a finite surface, or by a ring of wire laid close upon the tube, the phosphorescence takes the form, approximately, of the evolute of an ellipse. In all these cases the illumination is somewhat irregular; but the geometrical elements of which the phosphorescent figure is composed, and the stripes or striations of more intense light, are always formed at right angles to the longer dimension of the contact piece. This being so, suppose that we place on the tube a strip in such a curve that the normal planes to the curve will pass through the tangent at the corresponding point of the image of the curve, *i.e.* the curve on the opposite side of the tube, each point of which is exactly opposite to a point on the tinfoil. In such a case all the striations will lie along the curve formed by the locus of the central patches of phosphorescence, and the result will be a single bright curved line of phosphorescence without any spreading out or striated margin. The curve fulfilling these conditions will be a helix, whose pitch is half a right angle. Experiment confirms the anticipation.

One more step in the study of these molecular streams is necessary for our present purpose, namely, an application to them of the same method which we have used with the electrical discharges themselves; viz. we must examine the effect of an inductive stream produced *ab extra* upon a direct stream due to the discharge inside the tube. These effects may be described generally as the interference of molecular streams.

If the finger be placed upon a highly exhausted tube through which a discharge with a positive air-spark is passing, the phosphorescence due to the molecular streams from the negative terminal is seen to fade away from the place where the finger rests, and from a region lying thence in the direction of the positive terminal. The effect is that of a shadow over that part of the tube; and as this is produced not by any real intervening object, but by an action from outside, we have termed it a "virtual shadow." The phenomenon is due to a beating down of the streams of molecules coming from the negative terminal, by the transverse streams from the side of the tube immediately within the part touched.

The interference of two molecular streams may be further illustrated by a variety of experiments, and in particular by arranging within the tube a conductor of some recognisable form —say skeleton tetrahedron. If the tube be touched at a place opposite to this object a shadow of the latter will be formed in the relief phosphorescence; but if the tube be touched also at a point on which the conductor rests, the shadow will be splayed out in a striking manner. This splaying or bulging of the shadow is due to the interference of the molecular streams issuing from the surface of the conductor, which then acts as a *quasi* negative terminal, with the original relief streams issuing from the first point of contact.

With the help of these properties we are able, by connecting a patch of tinfoil on the tube with earth, or with the negative terminal itself, or with a second patch elsewhere on the tube, to detect the presence or absence of a demand for negative electricity; to localise the main seat of such demand; and even to compare the electrical condition of different parts of the tube at the same time or of the same parts at different times during the very passage of the discharge. In this way we approach the question of the small time-quantities involved in the discharge.

And, in the first place, it must be understood that the whole duration of one of these intermittent discharges is comprised within a period of which the most rapidly revolving mirror has been incompetent to give any account. It may be in the recollection of a few of my audience that when the discharge from my great induction-coil was exhibited at the Royal Institution with tubes on a revolving disk the discharge showed a durational

Digitized by Google

character as long as the coil alone was used; but as soon as a Leyden jar was introduced, which was in the main equivalent to an air-spark in a continuous current, the durational character disappeared, and nothing was visible but a bright line, the width of which depended, not upon the duration of the discharge, for no velocity of rotation in any way affected it, but only on the width of the slit through which the discharge in the tube was seen. But, notwithstanding the extreme rapidity with which the discharge is effected, our experiments have already shown that the spark or discharge is a complicated phenomenon, the various parts of which take place in a certain order or sequence of time; and that in virtue of this sequence we have succeeded, at the various pressures comprised within our range, in affecting and modifying it *in transitu*. This suggested the idea that, although the subject is surrounded with difficulties, it might still be possible to form some relative estimate, at all events, of the time occupied by the various parts of which the whole phenomenon is composed. And in fulfilment of this the following are some of the conclusions to which we have been led.

The time occupied in the passage of electricity of either name along the tube is greater than that occupied in its passage along an equal length of wire.

This may be shown by connecting metallically a piece of tinfoil near the air-spark terminal with another near the distant terminal; for it is then seen that the former derives as much relief from the latter as if the latter were not on the tube. This shows (1) that at the time when the electric disturbance reached the nearer piece of tinfoil the more distant piece was unaffected, and (2) that the disturbance propagated along the wire reached the second piece before the arrival of the same disturbance propagated within the tube.

The negative discharge occupies a period greater than that required by the particles composing the molecular streams to traverse the length of the tube, but comparable with it.

Proofs of this proposition are to be found in the phenomena of virtual shadows, and in other instances of the interference of molecular streams; but, omitting detailed experiments, the general argument on which the above conclusion is based is as follows: If two molecular streams, one issuing with positive relief from the side of the tube, the other coming from the negative terminal, show signs of interference, it is clear that the former of these, which certainly started first, must have continued to flow, at all events, until the arrival of the latter.

The time occupied by the passage of electricity of either name along the tube is incomparably shorter than that occupied by the emission of the molecular streams, or (what is the same thing) the time occupied by the negative discharge.

In support of this conclusion we have time only to mention a single experiment. If two pieces of tinfoil connected by a wire be placed, one near the negative, the other near the positive end of a tube through which a negative discharge with a rather long air-spark is passing, the former will show relief (positive) effects, the latter special (negative) effects; but no phosphorescence will be caused at the latter, however long the air-spark used. When the second patch is lifted off the tube and placed upon another through which no current is passing, phosphorescence is immediately produced. The explanation of this appears to be as follows: The negative electricity, bursting into the tube, summons all the positive which it can draw from the tinfoil. This is answered so promptly, that the second patch gives up to the first through the medium of the wire all the positive that it can yield, or, which is the same thing, draws off from the first all the negative that it can obtain; and this is done before the advancing negative reaches the distant patch. But so rapidly does the negative advance, that it reaches the distant patch before the molecular streams have had time to flow from the latter in a sufficient stream to produce phosphorescence; and it reaches it in time to revoke the supply of positive to the nearer, and to draw back the supply of negative which would have come to, and with it the molecular streams which would otherwise have flowed from, the further patch. When the second patch is placed on an independent tube, where no such revocation is possible, phosphorescence actually appears, showing that the revocation is no mere supposition, but a real phenomenon.

From the last two laws it follows as a consequence that negative electricity, and therefore also electricity of either name, in the tube outruns the molecular streams.

We may now fairly ask whether the phenomena which we have been studying have any counterpart in the larger operations of nature which are going on around us, and whether the conclusions to which we have been led afford any explanation of observed facts? Many natural phenomena doubtless fundamentally depend upon electricity; how many we hardly yet know. But there are two in particular, namely, lightning and the aurora, which are unquestionably electrical, and whose correspondence with the spark proper, and with the discharge in rarefied gases, respectively has often been noticed. On this we venture to offer a few remarks.

To say that both of these phenomena are dependent on the electrical state of the atmosphere is not saying much; both for other reasons, and especially because we do not know upon what atmospheric electricity itself depends. But it is clear that, as to a knowledge of the distribution of such electricity the aurora must look for a proximate, as well as an approximate, explanation of the facts.

In a thunder-cloud we have an aggregation of aqueous particles small enough to remain, temporarily at least, suspended in the air. All of these, it would appear, are similarly electrified, and by their mutual repulsion are restrained from further coalescence. By their presence the ground below the cloud becomes inductively electrified in the opposite sense; and as soon as the cloud by its motion comes within sparking distance, or by an increase of its charge attains sufficient tension, a spark discharge takes place, which, as we have seen above, is a flash of lightning. A similar action may naturally take place between two clouds oppositely electrified. The electrical tension required for a flash of lightning is of course enormous. It has been calculated that in order to produce directly from a battery of the most favourable construction a spark of 42 inches, equal to that given from my great induction-coil, from 60,000 to 100,000 cells would be necessary; while for a flash of lightning a mile long more than 3,500,000 cells would be required.

In some interesting experiments on water flowing from a small orifice in a cistern Lord Rayleigh has found that the breaking of the continuous column into drops is checked by communicating to it a small charge of electricity; but that it is promoted by a large charge. We may imagine with him that something of the same kind takes place in the cloud; and that before the flash the aqueous particles are kept apart by mutual repulsion due to their being all highly charged with electricity of the same name; and that after the flash they are left either without charge or with so slight a charge as to promote their coalescence and the consequent fall in the form of rain. This would be an explanation of the well-known downpour which frequently occurs after a flash of lightning.

There is moreover another form of lightning to which the discharge in our vacuum-tubes offers, to say no more of it, considerable analogy, namely, that commonly known as ball lightning. The appearance of ball lightning is described as that of a luminosity or ball of fire moving generally towards the earth in a direction more or less oblique, and disappearing in most cases before reaching the ground. In some tubes, the exhaustion of which is very moderate, say, having a pressure of several centimetres of mercury, it happens not only that the Llocks of striated termed entities by Mr. De La Rue are formed, but also that these entities travel along the tube from the immediate neighbourhood of the positive terminal to a finite distance in the direction of the negative, and then disappear. It would seem not unreasonable to suppose that ball lightning is due to conditions not dissimilar to those of such tubes, namely, to a discharge occurring in the upper regions of the air, at an elevation of perhaps twenty miles, more or less, where the pressure is moderate, that is to say, greater than that under which an auroral display could take place, and yet less than that which would give rise to a true spark or ordinary flash of lightning. As further we effect the discharge in the tube by the gradual pouring of electricity from a charged Leyden battery, or by condenser, through a suitable resistance, or if we use an induction-coil, then the condenser, or coil, will represent the charged cloud, or portion of the atmosphere, from which the phenomenon proceeds; and the analogy will perhaps be considered sufficiently close to render further observations in proof or disproof of the theory desirable.

Let us now turn to the aurora. Sufficient experiments have been made this evening to show that the discharge in rarefied gases differs from that in gases at higher pressures; and that the difference corresponds exactly to that observed between the diffused, gentle, and flickering play of the aurora and the sharp crashing spark of a flash of lightning. It is also abundantly clear that at an elevation of twenty or thirty miles above

Digitized by Google

earth's surface the atmospheric rarefaction must be such as to convert what would be lightning at a lower leve into a discharge similar in the main to that in a vacuum tube.

Further, it is an ascertained fact that a difference of electrical condition in different portions of the atmosphere often prevails. We have, therefore, not unfrequently present in regions at moderate elevations, say from twenty to fifty miles, all the conditions necessary for the production of an auroral display.

And not only so, but our experiments enable us to determine, at all events approximately, some limits of elevation within which this phenomenon can occur, and thereby to check the very divergent estimates of those who have observed it. Estimates of the altitude at which the auroral discharge takes place have been made from simultaneous observations at different points, and these have ranged up to fifty or sixty, and even to 281 miles. But even the lowest of these appears to be improbable. The pressure at which the resistance of air is least is a little less than ·4 of a millimetre of mercury; and the corresponding elevation is about thirty-eight miles. A vacuum tube measured by hundred-thousandths of an atmosphere would correspond to an elevation of a little more than eighty-one miles. Through a hydrogen vacuum at this pressure Mr. De La Rue failed to obtain a discharge with 11,000 cells; and he adds that "it may be assumed that at this height the discharge would be considerably less brilliant than at thirty-eight miles, should such occur."

It seems to be a well-ascertained fact that in high latitudes there are fewer thunderstorms and more auroras than in lower latitudes. This fact points to the conclusion that, after a disturbance, the re-distribution of atmospheric electricity is effected by one process or by the other, according to, or rather in consequence of, the meteorological differences between arctic, temperate, and tropical regions. In colder regions, where the air is generally drier, and, consequently, a better insulator than in warmer, there is less liability to a discharge taking place in the lower and denser strata; that is, there is less liability to lightning. But at higher levels the rarefaction may compensate this, and cause an auroral discharge to take place instead.

There are other features in which a comparison may be made between the auroral light and vacuum discharges. These discharges, when free to arrange themselves in a magnetic field, follow the lines of force; the auroral streamers appear to run parallel to the dipping needle. The colour of such discharges varies with the exhaustion; that of the aurora varies, like that of an air-vacuum, from red almost to white; and in the absence of independent observations to the contrary, we may fairly attribute the variety of tint in the aurora partly to a diversity of elevation, and, consequently, of rarefaction in the region where it takes place, but partly also perhaps to the electrical conditions present anterior to the passage of the discharge.

These and other features of the phenomenon of the aurora, as well as the kindred subjects of earth currents, the disturbances of the magnetic needle, and the connection of the whole with solar radiation as a predisposing cause, have been brought together under one theoretic view by Prof. Stokes, to whom I am indebted for much of what I have here said on the subject.

Having thus gone through, so far as circumstances permitted, the experimental and inductive parts of my subject, it might have been very pleasant to have cast aside for a few moments the links which connect strict induction with what may be termed the fixed points of ascertained fact; and, restrained only by the more elastic bonds of scientific imagination, to have indulged in speculations about things still lying on the borders of science and of dreamland. But I must leave each of you to follow out this vein of thought after your own fashion; and, confining myself to a single remark, I will simply indicate the direction in which my own thoughts on the present subject are inclined to turn. The remark is this: If in the search for a solution of the mystery of electricity there be one element more deserving our attention rather than another, it is that of time. We have utilised this element in our experiments with the revolving mirror; and we have touched upon its more subtle influences in our conclusions about the small time quantities in relation to the discharge.

All operations of nature take place in time. It is in the time-sequence of phases, often apparently simultaneous, but in reality successive, that we may hope to strike the origin of many complicated phenomena. Time is the ocean beneath whose waves and whose currents the secret fountains of truth are to be sought. Time is the ocean whose mighty stream encircles our life. Time as the ocean whose "countless smiles" gave birth to Venus and the Nereids and all the infinite forms of beauty and of brightness which play around our youth. Time is the ocean from whence sprang also the steeds of Neptune, typical of the strength of our more mature years. Time is the ocean in whose loving arms we fall asleep, when the sun sinks low on the horizon, and the shades of night are creeping over the heavens, and all things tell us that our course is run.

BIOLOGY AS AN ACADEMICAL STUDY[1]

II.

IT may help to the understanding of what I mean by a sound method of biological teaching if I give a brief outline of the course of study I hope to pursue with my students this session. It is hardly necessary for me to state that this course is derived from Prof. Huxley's by a natural process of descent with modification.

In the first place there will be some four or five lectures on a common flowering plant, giving an account of its ordinary structure as seen by the naked eye, of its microscopic structure, of its physiology, and of the process of its development. After each lecture the students will examine for themselves the plant described, learning not only to dissect it in the ordinary way, but to make preparations for the microscope. By this means they will be familiarised with the use of the microscope, the employment of staining fluids, and other reagents used in the investigation of minute structure, and with the chief processes of manipulation. As the laboratory will be open for nine hours a week, so as to give three hours for working out what has been described in each hour's lecture, it is to be expected that a student of average intelligence will, by the time this part of the course is over, have a very fair notion of what a flowering plant is, of the processes by which its life is carried on, and of the manner in which it originates.

The next few lectures, and the corresponding portion of the practical course, will be occupied with a similar treatment of an animal: the one selected, as on the whole the most convenient and the most instructive, being the common sea crayfish of our markets. In the examination of this organism, the students will learn something of the art of dissection, and will further apply the knowledge of microscopic structure which the study of the plant has given them, to the far more difficult problems of animal histology. The study of the crayfish, and the comparison of it, point by point, with the plant, should give a clear conception of the main points of difference and of likeness between the more highly organised animals and plants—between animals and plants as they are generally known to us.

In dealing with these types in the lectures it will be my aim always to proceed from the known to the unknown; to begin with points which every one who has seen a flowering plant or a crayfish must have noticed, gradually leading up to such points of structure as require minute observation to verify them, and above all never to give a definition or a general statement without first supplying the facts from which it is legitimately deducible.

Next, I propose to take a number of types selected on the one hand from the lowest plants, on the other from the lowest animals: to show how these unicellular organisms agree in structure and in the nature of their physiological processes with the individual cells of which the bodies of the higher plants and animals are made up, and to point out how, in dealing with these lowest members of the two kingdoms of organic nature, the boundary line between the two kingdoms tends to disappear, and it becomes very difficult, sometimes even impossible, to say what is a plant and what an animal. The study of these lowly forms will also lead to the question of the origin of life, and it will be necessary to say something of the attempts which have been made to establish the doctrine of spontaneous generation, and to discuss their value.

The consideration of a few other animal and vegetable types, especially such as, although multicellular, exhibit none of the complex tissues found in the higher animals and plants, will bring the introductory part of the course to a close—the part which deals with the general facts and principles of biology. In it the student should learn how animals and plants agree with and differ from each other, and from inorganic bodies; what are the relations of animals and plants to one another, and to

[1] Inaugural Lecture delivered in the University Library, May 2, 1881, by T. Jeffery Parker, B.Sc., Lond., Professor of Biology in the University of Otago. Continued from p. 546.

Digitized by Google

inorganic nature; what is meant by differentiation of structure, and by the division of physiological labour exhibited by the higher organisms in contradistinction to the lower. He will also have gained some conception of the all-important truth that the higher organisms begin life as a simple cell, comparable to an entire unicellular organism, and that, of that cell, the animal or plant itself, as well as every element of its fully-formed tissues, is a lineal descendant. And these matters will be impressed upon his mind by actual verification of all the more important points; so that he will, it is hoped, have begun to learn the first duty of the student of science—to take things on trust only so long as he is unable to bring them to the test of observation and experiment.

The whole of this part of the course is a modification, adapted to local requirements, of Prof. Huxley's well-known "Genera Biology" course. It will be seen at once that it serves as an introduction both to botany and zoology, forming a starting-point from which lectures on both these subjects may diverge. I hope to give a few lectures on structural botany on Monday evenings, but the remainder of the ordinary biology course will be purely zoological, dealing chiefly with animal morphology, or comparative anatomy, as opposed to systematic zoology. It is gradually being acknowleged by those most competent to form an opinion, that zoology in this latter sense is a subject of no educational value whatever—I mean as far as the beginner is concerned—since it necessarily follows a course exactly the opposite of that which the scientific novice should pursue. It begins with generalisations, and ends with details; it provides elaborate systems of classification without giving even an elementary knowledge of the totality of organisation of a single animal, and—what is most mischievous for the beginner—it regularly ignores facts not of "classificatory importance," and so tends to offer a premium on superficiality.

The principal groups of animals will therefore be treated partly by the description of "types," selected as exhibiting the chief characteristics of the group, partly by the comparative method—that is, by taking up a particular organ or set of organs and tracing the modifications it presents through a series of groups. The more important fossil members of any division will be considered along with the recent forms, a good deal will be said of the embryology or development of the chief types, and the main facts of their distribution in space and time will be considered, as well as the question of classification and the principles upon which it is conducted.

From time to time the necessity will arise of discussing the relations between these several divisions of the subject and the explanations of them. It will be shown, for instance, that a proximate explanation of the extraordinary changes undergone by an animal in its development from the egg is afforded by the theory that the evolution of the individual is a recapitulation—much abbreviated and distorted—of the evolution of the species. Or, to take another example, it will be pointed out that in the doctrine of evolution we have the only satisfactory explanation of the fact that in tracing back the history in past time of many groups, the boundaries between them tend to disappear, and species are found at last assignable to no existing group, but combining in themselves the character of two or more. As a striking example I may mention the recent discovery of the second known specimen of the fossil called *Archæopteryx*, hitherto supposed to be a true bird, although exhibiting certain approximations towards reptiles. It is now known that Archæopteryx is completely intermediate between reptiles and birds—that it is indeed a feathered reptile; and it cannot be doubted that we have here clearly indicated the line of descent of the group of birds, at the present day so sharply separated from all other vertebrate animals. In the same way the mammalia, when traced back to the earlier tertiaries, are found to be represented by animals which are neither marsupials nor rodents, carnivores nor herbivores, but form a common group of generalised forms, from which the well-marked orders of mammals as we know them to-day are seen gradually to diverge as we trace the fossils from the lower to the upper tertiaries.

While this the greater part of the course is going on, the laboratory work will consist in the dissection of one or more common animals selected as types of each of the chief groups. The Mollusca, for instance, will be illustrated by the cockle or mussel, the slug, and perhaps the octopus; the great group of articulated animals by the crab, sandhopper, beetle, moth, spider, millepede, &c.; the Vertebrata by some common fish, such as the red cod, by a frog if it can be had, by a pigeon and a rabbit. In this way the student will become familiar with the entire organisation of a sufficient number of animal types to enable him to understand the description of other types given him in lectures or in books. Further illustrations of many points of importance will be afforded him by the examination of specimens from the museum, notably in the case of fossils, and in that of the skeleton, which latter, apart from its purely scientific importance, affords an excellent training for the faculties of observation, comparison, and of memory. Moreover, if the time holds out I hope to be able to let the students see for themselves some of the chief stages in the development of the common fowl—the most convenient starting-point for the study of embryology.

Lastly, from time to time short practical examinations will be held. Subjects will be provided differing from those already seen, and the student will be encouraged to investigate their structure without help, and to compare the results thus obtained with those of the more formal work.

I think no one will doubt that a course of this sort must furnish a true discipline. Whether as a discipline it is superior *cæteris paribus*, to a classical course—to a study of the grammar and construction of the Latin and Greek languages, and a certain acquaintance with their literature, I must leave to the decision of those who know more of the latter subjects than myself. Certainly a consideration of the faculties the two studies are likely to bring into play, train, and develop, leads one, in the absence of other data, save the sad memories of one's own school work, to assign a distinctly higher value to scientific than to grammatical study as a mental training. But this point has been so often insisted on by men whose words carry weight that no remarks of mine are needed. What I consider it my business to point out is the way in which a course in my own branch of natural science should, and the way in which it should not, be carried on, and I feel convinced that even those who have a knowledge of the subject will see that the training afforded by the course of which I have given a brief outline in observation, in induction and deduction, in the comparative method, and in the true understanding of the relations between cause and effect, is not easily surpassed, to say nothing of the less important, though by no means to be despised, training of the memory, and of the exercise of the imagination provided by theories of molecular structure, and their application to morphological and physiological problems.

As to the effect of these studies upon still higher faculties, I feel that I cannot do better than quote a well-known passage from a lecture of Prof. Huxley's, delivered nearly twenty-seven years ago. He says:—"There is yet another way in which natural history may, I am convinced, take a profound hold upon practical life, and that is by its influence on the finer feelings and the greatest of all sources of that pleasure which is derived from beauty. I do not pretend that natural history knowledge, as such, can increase our sense of the beautiful in natural objects. I do not suppose that the dead soul of Peter Bell, of whom the great poet of Nature says—

> "'A primrose by the river's brim
> A yellow primrose was to him,
> And it was nothing more,'—

would have been a whit removed from its apathy by the information that the primrose is a dicotyledonous exogen, with a monopetalous corolla and central placentation. But I advocate natural history knowledge from this point of view because it would lead us to *seek* the beauties of natural objects instead of trusting to chance to force them on our attention."

Indeed the elevating effect of science from this point of view is of quite the same nature as that of art, and with the alteration of a word or two the sentence put by Browning into the mouth of Fra Lippo Lippi expresses exactly the same idea as the passage I have just quoted:—

> "For don't you mark?—We're made so that we love,
> First when we see them painted, things we have passed
> Perhaps a hundred times, nor cared to see;
> And so they are better painted—better to us,
> Which is the same thing. Art was given for that."

One may even go a step further and say, with the Laureate, that he who could know all about one single little flower would know "what God and man is."

I would draw attention to the fact that I have said nothing as to what is often called the practical bearing of scientific instruction. And this purposely; for we who have the charge of higher education in the ordinary sense—as distinguished from professional or technical education—have nothing whatever to do with so-called practical ends. Our business is, as far as possible, lies, to train the minds of our students—to teach them to think and to learn for themselves, knowing that whatever career [illegible]

scientific amateurs, men who, while engaged in professional or business pursuits, devote their spare time to the advancement of some branch of natural knowledge. And I think I am justified in saying that New Zealand has hitherto been pre-eminent among the Colonies for following out in this respect the traditions of the Mother Country. To say nothing of botany, many groups of animals have already been thoroughly well worked up, and considerable headway has been made with others; but "there remaineth yet very much land to be possessed," and one may venture to hope that workers from this University will before long begin to swell the *Transactions* of the New Zealand Institute and the publications of the Geological Survey. Upon any who may have this laudable ambition before them I would venture to urge the advisability—I might almost say necessity—of acquiring a sound and exact, although necessarily elementary knowledge of biology as a whole, before beginning to study any special branch. The work of a man who knows his own limited branch of science, and nothing beyond, is quite sure to be imperfect, and will most probably be evanescent. The highest results are only to be obtained by studying a group or a species, not only in and for itself, but in connection with other groups or species, by keeping always in mind the possible connection of one's own results with those of others, by remembering that the objects one is studying are not isolated things like coins or postage-stamps, but are *organisms*, whose special characters have been impressed upon them by forces which have been at work from the beginning of all things.

Finally, it is just possible that some day one of our students may be brought to take up biology as a career. I need hardly say that such a one, besides completing his studies elsewhere, would be probably compelled, unless possessed of private means, to exercise his profession either in Europe or in America, since there is very little chance at present of more than one biological appointment in a decade falling vacant in this Colony. But a man with a love for his subject and not afraid of hard work, who, after learning all he could learn here, availed himself of the best teaching at home—at London, Cambridge, or Heidelberg—would, I feel convinced, have every chance of success. He would never get rich; the present practical applications of biology are not such as insure fortunes. He would have all his life to be satisfied with an "*aurea mediocritas*" in matters of finance, but he could count upon what is even better than a large income—increasing joy and constant development through a thoroughly congenial life-work.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—The Colleges meet on Saturday, October 15, and the professorial lectures begin the following week. The professors and lecturers in physics have drawn up the following scheme of lectures and classes for the Michaelmas term:—Prof. Clifton lectures on Wednesday and Saturday on terrestrial magnetism, and Prof. Bartholomew Price lectures on Tuesday, Thursday, and Saturday on the dynamics of material systems. Mr. Hayes lectures on electrostatics (treated mathematically). Instruction in practical physics is given daily in the Clarendon Laboratory, under the direction of Prof. Clifton, Mr. Stocker, and Mr. Heaton. Mr. Stocker gives an experimental lecture on elementary mechanics, and Mr. Heaton has a class for problems in elementary mechanics and physics. The above lectures are given in the University Museum. At Queen's College Mr. Elliot gives a course on geometrical and physical objects; at Christ Church Mr. Baynes gives a course on elementary heat and light; and at Balliol Mr. Dixon gives a course on elementary magnetism and electricity.

On Tuesday the Fellows of Wadham College elected Mr. G. E. Thorley to the wardenship of the College, in place of Dr. Griffiths, resigned. It is understood that Dr. Griffiths will continue to reside at Oxford, and will remain a delegate of the University Press and of the Local Examinations.

An examination for Natural Science Scholarships begins on Thursday, October 13, at Exeter and Trinity Colleges. The scholar elected at Exeter will be expected to read for honours in the biological school, and the scholar elected at Trinity will be expected to read for honours in chemistry or physics.

An election to a Brackenbury Natural Science Scholarship at Balliol College will be held in November. Papers will be set in physics, chemistry, and biology. Candidates may offer themselves in two of these subjects, and may also take mathematics or an English essay.

CAMBRIDGE.—Prof. Paget will lecture on Clinical Medicine at the Hospital this term; and Prof. Latham on the Physiological Actions and Therapeutic Uses of Remedies, at Downing College.

Practical Anatomy commenced at the Dissecting Room on October 5; and demonstrations for second year men on October 7. Prof. Humphry's lectures on the Organs of Digestion begin on October 13. A class in anatomy and physiology, preparatory for the second M.B. and the Natural Sciences Tripos, will meet for the first time on October 17.

Prof. Liveing lectures this term on the General Principles of Chemistry, and also on Spectroscopic Analysis, taking limited classes at successive hours on the latter subject; there will be both practical observation with spectroscopes, and explanations of principles and results. Prof. Dewar will lecture three times a week on Physical Chemistry, beginning October 14; and two tutorial lectures weekly will be given in connection with these lectures by Mr. A. Scott, the professor's assistant. Investigations may be carried on in the laboratories, with the approval of the professors. Demonstrations in Volumetric Analysis will be given by one of the demonstrators three times a week.

Mr. F. M. Balfour will give two courses of lectures (elementary and advanced) on Morphology, with practical work, at the New Museums, each course to extend over two terms. Both courses will be on the Invertebrata this term.

Dr. Vines commenced his lectures on the Physiology of Plants at Christ's College on October 12.

Prof. Stuart lectures on Mechanism three times a week; the workshops and drawing office open on October 14. Mechanical drawing and machine designing will be taught in the drawing office; and the use of tools, the elements of practical engineering and the construction of physical instruments in the workshops.

Prof. Lewis has two courses this term, one on Descriptive Crystallography, and the other on the principal minerals known as rock constituents.

Lord Rayleigh lectures on Electricity and Magnetism; Prof. Cayley on Abel's Theorem and the Theta-functions; the deputy Plumian Professor on Practical Astronomy.

SOCIETIES AND ACADEMIES

LONDON

Entomological Society, September 7.—Mr. H. T. Stainton, F.R.S., president, in the chair.—Rev. A. E. Eaton exhibited a dried specimen of the nymph of a species of *Ephemeridæ*, a genus of *Ephemeridæ* previously known only in the adult condition.—Mr. E. A. Fitch exhibited a larva of *Zeuzera æsculi*, infested with a species of *Encyrtus* in extraordinary numbers; specimens of a fly (*Drosophila cellaris*) bred from a bottle of pickles; a series of interesting galls (*Cecidomyidæ*), and some stems of *Equisetum* in which larvæ of *Dolerus æglanteræ* were feeding.—Mr. T. R. Billups exhibited six new British *Ichneumonidæ*.—Mr. C. O. Waterhouse exhibited a specimen of the common mouse attacked by the larva of an *Œstrus*.—Sir S. S. Saunders exhibited specimens of *Sarcophaga lineata*, Fall., which destroys locusts in the Trend, and of *Chalcis flavipes*, Panz., parasitic on the parasite itself.—The president read a letter from the Colonial Office respecting the report forwarded by the Society on locust parasites.—Mr. C. O. Waterhouse read descriptions of some new *Coleoptera* from Sumatra.—Mr. J. S. Baly communicated descriptions of some new species of *Eumolpidæ*; and Mr. A. G. Butler communicated a list of butterflies collected in Chili by Mr. T. Edwards.

PARIS

Academy of Sciences, October 3.—M. Wurtz in the chair.—M. Dumas communicated the decisions recently come to by the Congress of Electricians on electrical standards. He also exhibited an ingot of steel produced by Dr. Siemens in the Exhibition, by electric fusion (in fourteen minutes) of a few kilogrammes of steel in a magnesia crucible. The expenditure of fuel to drive the machine was less than that required by direct fusion in a common furnace.—On the secular displacements of the planes of orbits of three planets, by M. Tisserand.—Public experiments on vaccination of symptomatic *charbon*, made at Chaumont (Haute-Marne) on September 26, 1881, by M. Bouley. Symptomatic charbon is proved to be distinct from bacteridian charbon; *inter alia*, the microbe of the former, introduced into the veins, insures future immunity, producing at the time only slight fever. This vaccination of MM. Arloing, Cornevin, and Thomas, differs from that of M. Pasteur in that the natural virus is used in all its energy (not attenuated). Care has to be taken not to let the virus enter cellular tissue, but only the (jugular) vein. The experiments were on 25 young cattle, 18 of which and the results distinctly vindicate the injection the cannula was deeply inserted a new application of the equation of Observations of the comet of 1881 (Wolf made at Paris Observatory, by M. Bo radiophony or telegraphy; multiple t phone, by M. Mercadier. (This was May 30.) ENGLISH MEN OF LETTERS.
Edited by JOHN MORLEY.

LANDOR. By Professor Sidney Colvin.
"Besides being admirably written it is thoughtful, critical, and full of honest work."—*Athenæum.*

DRYDEN. By G. Saintsbury.
"It is, beyond question, the best account of Dryden which has yet appeared."—*Academy.*

WORDSWORTH. By F. W. H. Myers.
"Mr. Myers gives us a picture of the man and an estimate of his work which is certainly not inferior to anything that has preceded it."—*Academy.*

LOCKE. By Professor Fowler.
"A pen more competent than Professor Fowler's for this particular work might have been sought, and sought in vain."—*Examiner.*

BYRON. By Professor Nichol.
"Decidedly one of the most careful and valuable of the whole series."—*Athenæum.*

POPE. By Leslie Stephen.
"The writer's eminent qualities as a critic, his judgment, his wit, his abundant knowledge of eighteenth-century literature, and his keen enjoyment of literary Form, have equipped him handsomely for the task he has undertaken."—*St. James's Gazette.*

COWPER. By Goldwin Smith.
"Mr. Goldwin Smith has sketched, in a few decisive touches, the genius of the poet and weakness of the man."—*Daily News.*

CHAUCER. By Professor A. W. Ward.
"Far away the best connected account of Chaucer and his works to be found in English."—*Academy.*

BUNYAN. By J. A. Froude.
"He has given us a real study of Bunyan's life and character, and at the same time a real study of his books."—*Athenæum.*

SOUTHEY. By Professor Dowden.
"A truly scholarly and delightful monograph."—*Examiner.*

HAWTHORNE. By Henry James, Jun.
"He has made a careful, conscientious, and even vivid literary portrait, such as few of our own writers could have made."—*New York Nation.*

MILTON. By Mark Pattison.
"He has put life into old facts, he has taken an impartial estimate of a great man whose name is too often used for purposes of poetry."—*Spectator.*

JOHNSON. By Leslie Stephen.
"It could hardly have been done better."—*Pall Mall Gazette.*

SCOTT. By R. H. Hutton.
"We could not wish for a more suggestive introduction to Scott and his poems and novels."—*Examiner.*

GIBBON. By J. C. Morison.
"As a clear, thoughtful, and attractive record of the life and works of the greatest among the world's historians, it deserves the highest praise."—*Examiner.*

SHELLEY. By J. A. Symonds.
"The lovers of this great poet are to be congratulated at having at their command so fresh, clear, and intelligent a presentment of the subject, written by a man of adequate and wide culture."—*Athenæum.*

HUME. By Professor Huxley, F.R.S.
"It may fairly be said that no one now living could have expounded Hume with more sympathy or with equal perspicuity."—*Athenæum.*

GOLDSMITH. By William Black.
"Mr. Black brings a fine sympathy and taste to bear in his criticism of Goldsmith's writings"—*Athenæum.*

DEFOE. By W. Minto.
"Mr. Minto's book is careful and accurate in all that is stated, and faithful in all that it suggests."—*Athenæum.*

BURNS. By Principal Shairp.
". . . None of the series has given a truer estimate either of character or of genius than this volume."—*Spectator.*

SPENSER. By the Very Rev. the Dean of St. Paul's.
"Dr. Church is master of his subject, and writes always with good taste."—*Academy.*

THACKERAY. By Anthony Trollope.
"Mr. Trollope's sketch is excellently adapted to fulfil the purpose of the series in which it appears."—*Athenæum.*

BURKE. By John Morley.
"It is no disparagement to the literary studies already published in this admirable series to say that none of them have surpassed, while few have equalled, this volume on Burke."—*British Quarterly Review.*

*** Other volumes in Preparation.*

ANTHROPOLOGY.

AN INTRODUCTION TO THE STUDY OF MAN AND CIVILISATION.

By Edward B. Tylor, D.C.L., F.R.S.

WITH NUMEROUS ILLUSTRATIONS.

"If all manuals were like this, a generation over-educated for its intellect would have no reason to complain. . . . The volume seems to us to serve a double purpose. It is a most attractive and entertaining introduction to the science of anthropology . . . Mr. Tylor has acquired the art of teaching. . . . His writing is clear and luminous, and his arrangement masterly. . . . Mr. Tylor writes with as much caution as learning."—*Saturday Review.*

"It is an endeavour to put before the lay reader in a clear, condensed, and interesting form the main settled results of modern investigations into the science of man. . . . Mr. Tylor has been eminently successful in writing a very comprehensive and yet readable book. . . . Mr. Tylor's admirable little book certainly deserves the success with which it will doubtless meet."—*Pall Mall Gazette.*

"To take in hand a chaos and reduce it to any ordinary plan; to examine the vast complex of human life in all ages and all stages, and to show how it may be treated under half a dozen main heads,—this is indeed a difficult task, yet it is one which Mr. Tylor has performed within very modest limits and with distinguished success. . . . It is neither dull nor abstract. On the contrary, every page is rich in concrete illustration and abundant colouring. Children could read the greater part of it and find it amusing, while men will find it suggestive in ideas and admirable in general arrangement. Indeed, it may be said that, though this little book is, Mr. Tylor has never shown his store of facts to better advantage. It is more complete and more systematic than his earlier and larger works, and it gives the results of his latest thinking in their fullest and most mature form. . . . In short, it is one of the best of the useful class of scientific works which aim at giving to the non-technical but cultivated public the best results of historical investigations as they appear to a leader of thought in the special science itself. . . . The illustrations deserve the highest praise for their fidelity and the admirable way in which they bring out the minor characteristics of race, presenting a striking contrast in this respect to most ordinary attempts at representing anthropological types. . . . On the whole Mr. Tylor's treatment of all the facts is as masterly and unexceptionable as it is simple and interesting. . . . On the whole the students who read Mr. Tylor's book may congratulate themselves upon having obtained so easy, pleasant, and workmanlike an introduction to a fascinating and delightful science."—*Athenæum.*

Unfortunately all ex-hat knowledge of the sciences ease their observing capacity. ivingstone or a Holub, a Preje-for such especially, as also for geography similar to that which Universities would be a decided , and especially for school pur-limit should be defined as to

the sphere of geography; the happy medium has, we think, been well struck by M. Elisée Réclus in his magnificent "Géographie Universelle," which, when complete, will no doubt form a mine for compilers of text-books.

One of the most valuable recent developments of geography is seen in the scheme conceived by the late Lieut. Weyprecht, for the establishment of a ring of Polar observatories. This is now close upon being an accomplished fact, as will be seen from the account we gave of the recent meeting of the International Polar Congress at St. Petersburg. As our readers are no doubt aware, many Arctic authorities are of opinion that the days of great and expensive national Polar expeditions are past, and that the money thus spent would be put to much better use by being devoted to the carrying on of a continuous series of observations. At various points around the Arctic area observatories will be established as near as practicable to the Pole, where a continuous series of observations will be taken, according to a common pre-arranged plan. These observations will be connected with meteorology in all its departments, with terrestrial magnetism, the aurora borealis, atmospheric electricity, the movements of the ice, biology, combined with geographical exploration where practicable. After a year or two of such observations we may then be able to compare and co-ordinate Polar conditions with those which prevail in regions further south. A vast array of data must necessarily be accumulated that cannot but be turned to valuable account by science. Our knowledge of the meteorology of the temperate zone can never be complete until we are well acquainted with Arctic conditions, and thus the work to be done at these observatories will have an important practical bearing. Not only so, but it is maintained that it is only when we have the knowledge which will be collected at these stations that we shall be in a condition to send out an expedition for the Pole itself with anything like scientific assurance of success. We cannot but regret, then, that England has no share in the scheme. The countries forming the International Association are Russia, Germany, Norway and Sweden, Denmark, Austria, the United States, and we believe Canada; France and Switzerland lend it their countenance, and Lieut. Bove's Italian Antarctic expedition is to some extent affiliated to the Association. Stations are to be established on the north coast of Siberia, Nowaya Zemlya, Spitzbergen, Jan Mayen Island, the west coast of Greenland, Lady Franklin Bay, and the neighbourhood of Behring Straits. The colony for Lady Franklin Bay, sent out by the United States, has already, we believe, reached its destination, and the others will probably be all at work next year.

While speaking of Arctic matters we must express our surprise at a journal like the *Pall Mall Gazette* talking of Polar exploration as a barren work. This of course depends on what one looks for in the way of results; if an immediate return in £ *s. d.* is looked for, the work is barren enough certainly, as barren as all purely scientific research seems at its first undertaking; though even the *Pall Mall Gazette* must admit that all the difference between the present and the past, materially and intellectually, is due to the ultimate results of this same barren work. And we are glad to see that Capt. Adams, the well-known Dundee whaler, again found time to take part in the

Digitized by Google

barren work of Arctic research while doing his best to fill his blubber tanks. He succeeded in sailing up Wellington Channel as far as has hitherto been done; visited the scene of the *Fury* and *Hecla* disaster, and brought home some interesting relics of the Franklin Expedition, as well as some additional information. He fell in with an Eskimo who remembers Crozier and his men, and from whom Capt. Adams seems to have obtained some additional information on the fate of the disastrous expedition. It cannot, however, amount to much after what has been done by the late Capt. Hall, and quite recently by Lieut. Schwatka; still, Capt. Adams deserves the greatest credit for attempting to increase our knowledge of the Arctic area at great risk to himself; he is evidently made of the right stuff. From the United States, we learn, an expedition is to be sent out as early as possible to endeavour to find the records of the Franklin expedition, which Capt. Hall always maintained would be found in the clefts of some rocks near the scene of the disaster. The results will be looked for with interest, and will at least tend to the promotion of knowledge. So also will the international search for the missing *Jeannette*, which it is rumoured may be undertaken next summer. The suggestion of Baron Nordenskjöld, deserving as it must be of every consideration, seems improbable; the bodies and the bottle of whisky found at the mouth of the Lena on September 13, 1879, could hardly have belonged to the *Jeannette*, which was seen steering for Wrangel Land on September 2—*i.e.* 1400 or 1500 miles away. Mr. B. J. Jenkins suggests that the *Jeannette* has been fortunate enough to get into open water not far from the Pole, and may turn up next year. There is no harm in hoping on to the last, as we are justified in doing after the experiences of the Austro-Hungarian Expedition.

What is the conception of geography entertained by our Geographical Society may be learned from the very interesting sketch of its history just published by Mr. Markham in connection with the jubilee of its foundation, which took place upwards of a year ago. The Geographical Society was founded on May 24, 1830. Its original objects were "to collect, digest, and publish interesting and useful geographical facts and discoveries; to accumulate a collection of books on geography, voyages, and travels, and of maps and charts; to keep specimens of such instruments as are most serviceable to a traveller, to afford assistance, instruction, and advice to explorers; and to correspond with other bodies or individuals engaged in geographical pursuits." All highly necessary and useful objects in connection with the advancement of knowledge. The Geographical Society absorbed the old African Association and the Palestine Club, and among its founders or first officers we find the names of Murchison, Robert Brown, Sir John Barrow, Admiral Smyth; and in its first list of Fellows some of the leading scientific men of the time. Mr. Markham complains that the Royal Society did so little for the promotion of geography before the Geographical Society came into existence; but it would have been beyond the functions of that Society to deal with the objects referred to above, and Mr. Markham admits that it really did a great deal to promote all that was most distinctly scientific in connection with geography. It must be admitted that the Geographical Society has very faithfully carried out its programme. It soon became popular, and after it recovered from the results of bad management and extravagant expenditure, rapidly increased in members and income, until now probably the most numerous, if not the most wealthy learned society in the world. Admiral Smyth established its financial prosperity, and, as every one knows, Roderick Murchison made it fashionable. It has now upwards of 3300 Fellows, and its receipts in 1878 amounted to 8600*l.*, while the Society's funded capital was 18,500*l.*, not to mention the value of its fine premises, library, maps, &c., in Savile Row. Notwithstanding this material prosperity and its weakness for showing travelling lions, the Geographical Society has really done much for the promotion of exploration and geography. Directly or indirectly it has been connected with all the expeditions of importance that have gone out from England since it was founded; it has encouraged explorers by grants of money amounting in the aggregate to a considerable sum; it has bestowed its medals and other rewards on explorers and geographers of various nationalities, all of them men who had really earned such honours; it has been of much service in instructing explorers in the technicalities of their business, and recently has established a sort of school for topographical observation; it has accumulated a valuable library and collection of maps, which are freely at the service of all who care to use them; and its *Journal* and *Proceedings* contain a vast amount of information, not simply relating to geographical exploration, but many of the papers relate to the more scientific aspects of geography. The Society has itself initiated or materially supported not a few expeditions of importance, one of the most productive being that which Mr. Joseph Thomson recently brought to so successful a conclusion. One of the most important functions undertaken by the Society is the yearly examinations in geography which it holds in connection with schools; and the papers set at these examinations are both comprehensive and scientific; in this direction the Society is doing really good work for the promotion of scientific geography. It may be remembered that the Council recently instituted an annual course of lectures on the more strictly scientific departments of geography, by men of acknowledged eminence in their subjects. Unfortunately the Council did not feel themselves encouraged to continue these lectures; but we venture to think they were too easily discouraged. Let them by all means have their fortnightly popular meetings during the season; but at the same time there is nothing to hinder them having also more esoteric meetings at stated intervals, at which original papers might be read or lectures given of a kind akin to those found so frequently in the proceedings of Continental geographical societies. In this way the Society would do much to encourage scientific geography, and be justified in claiming the rank of a really scientific society, which many of its well-wishers feel that it can hardly claim at present. Why, moreover, should the Council not at least lend their countenance to the great international scheme of meteorological observatories, and take some steps to induce our Government to take an active share in the work? They could easily do this without in any way fettering their action with reference to those great Arctic expeditions to which some of them appear to be so partial.

the extremely talented biolo-

gist whose loss we deplored almost exactly two years ago. The work contains, in a most convenient form for reference, a vast number of facts relating chiefly to the anatomy of birds and mammals, together with all the figures with which the several memoirs were originally illustrated, and a copious index. It has been ably edited, evidently as a labour of love, by Prof. Garrod's successor in the post of prosector to the Zoological Society, Mr. W. A. Forbes, with the assistance for the physiological portion of Prof. E. A. Schäfer. Mr. Garrod was all his life favourably circumstanced to a remarkable degree for pursuing biological research. He had from his earliest age the advantage of scientific associations and the best of educations, and was soon placed in an independent position, which enabled him to make the occupation of his life that which almost all others, even those holding most of the existing scientific appointments, can only do in snatches of time saved from the educational or administrative duties connected with their offices. Of all these advantages he fully availed himself; but considering he was only thirty-three years old at the time of his death, the amount of his already-published work when collected together is surprising, and causes the greater regret that he was not spared to continue what he had so well begun, especially as his editor tells us of the immense amount of material in notes and drawings which he had accumulated, besides that which was in a sufficiently finished state to see the light.

In these days, when so much is being said about the encouragement of scientific research, and so many experiments are being tried, both with public and private money, as to the best means of promoting this end, we cannot help making the reflection, before concluding our notice of this volume, on the great results that may follow a small expenditure judiciously and steadily devoted for a series of years to one object. If the Zoological Society had not in 1865 established its prosectorship, we should have seen little of the really solid advances in our knowledge of the anatomy of the two higher classes of vertebrated animals contained in the valuable memoirs of Dr. Murie, those collected in the present volume, and those now in the course of publication by Mr. Garrod's successor in the office.

THE DIAMONDS, COAL, AND GOLD OF INDIA

The Diamonds, Coal, and Gold of India. By V. Ball, F.G.S. 12mo. (London: Trübner, 1881.)

IN this handy little volume the author presents us with a compendium of the facts known concerning the occurrence and distribution of the three principal mineral products of India. The work being so designed that it may be used as a handbook to the detailed accounts published by the Geological Survey of India and by other authorities in numerous scattered publications to which full references are given. In the first chapter the different localities producing diamonds, including both active and abandoned mines, are noticed in some detail. These are grouped into three areas, the most southerly being that to which the name of Golconda is usually applied, although, as the author points out, that town is not actually in a diamond producing district, but was the staple place where the product of the district was bought and sold.

Digitized by Google

The actual mines are in the southern part of the Madras presidency, in the districts of Kadapah, Karnul, Kistna, and Godaveri. The second great tract, further to the north, lies between the Mahanadi and Godaveri rivers, the chief localities being at Sambalpur and Weiragud, eighty miles south-east from Nagpore, and at a few places in Chota Nagpore. The third great tract is in the vicinity of Panna in Bandelkhand. In addition to these a few small diamonds are reported to have been found near Simla. In all cases the diamonds appear to have been found in sandstones or conglomerates, or in the gravels derived from their alteration. These sandstones are referred in the southern localities to the lowest member of the Karnul formation, which as a whole is considered to be the equivalent of the lower part of the so-called Vindhyan formation of Northern India. An upper group of the latter, the Rewah conglomerate, being the diamond-bearing bed in Bandelkhand. There does not appear to be any authenticated instance of a diamond being found in India in other than sedimentary rocks. One case, however, at p. 49, where the matrix is said to be "a network of strings of calc spar inclosing laminæ and small lumps of green clay," suggests the possibility of the material in question being a decomposed basalt or basaltic tuff, and as such comparable with the South African occurrences. What the present total production of the mines may be we are left to guess; as far as can be gathered from the scattered notices collected by the author, the larger number of the mines are of historical interest only.

The second chapter, that on Coal, is mainly an abstract of the communications on this subject made to the Records of the Geological Survey of India by Mr. Theodore Hughes, and is rather behindhand in point of time. The latest information appears to refer to the year 1878-79. The arguments for and against the supposed Mesozoic age of the Indian coal-bearing rocks are given in abstract with great fairness, and the author's conclusion that "floras alone form an unsafe guide to the correlation" of the ages of rocks in different countries is probably the only safe one that can be drawn from the available evidence. As a mere question of stratigraphical position it is probable that these rocks represent the uppermost coal-measures (Permo-Carboniferous) of Europe. Any one acquainted with the smaller coal-basins in the south of Europe cannot but be struck with the numerous analogies between them and the Indian coal-fields, more particularly in the thickness and irregularity of the seams. The author's statement that the Ramgunj coal "may be described as a non-caking bituminous coal," is rather too general. It is true for the larger seams, but besides these are to be found others in which the caking property is as well developed as in any caking coal in the world. The coke produced is not of particularly good quality, which is however due to the large quantity of ash in the coals, but as to their caking capacity, there can be no doubt whatever. The estimation as to the quantity of coal available seems to be rather wild guesses in some cases, and one of these, for which the data are professedly given, is a good specimen of an arithmetical puzzle. They are as follows (p. 69):—

"The coal occurs in three principal seams . . . average total thickness of 16 feet . . . over an area of 8½ square miles. The amount of coal may therefore be estimated at 1,360,000,000 tons, and the available portion of this at 80,000,000."

How the largest of the above figures is obtained, i.e. what its relation to the smaller quantity may be, is certainly not apparent from the author's statement. An allowance of 94 per cent. for faults, waste, and unworkable coal, which the above figures lead to, seems rather large.

The chapter on Gold contains extracts from most of the published details on the occurrence of precious metals in India down to the Reports of Mr. Brough Smyth, and the latest remarks of Indian newspapers, which however are dated as far back as May, 1880. An original investigation of the author's as to the distribution of auriferous detritus in areas occupied by rocks of different characters is of interest. He found that the proportion of gold obtained was larger upon crystalline schists than upon gneiss and granite, a result which agrees with that generally obtained in other parts of the world. As it was predicted to him by his native workmen, it is difficult to see how the author arrives at his belief that gold washing in India affords an example of human degradation.

His evidence seems rather to show that the gold washers have a highly skilled and minute knowledge of the distribution of gold-bearing alluvia, but the value of such knowledge is diminished by the circumstance that the amount of such material available has been practically exhausted by the labours of many generations of workers through a period of 2000-3000 years. The great extent of old workings discovered in some of the Wynaad mines also shows that the "old men" were no contemptible workers as vein miners.

In the earlier part of the volume the work done by "amateurs" in Indian geology is somewhat pointedly contrasted with that of the "professionals," whose whole time is devoted to the subject. This is to be regretted, as is also the assumption of an air of finality for the work of the Indian Survey, which the nature of the work certainly does not allow. For instance, we are told in the same paragraph that the rocks of the Vindhyan formation are absolutely azoic, and that they may be of any age, from Lower Silurian to Carboniferous; the real meaning of this expression being that no fossils have as yet been found in them. In this sense the New Red Sandstone might be said to be azoic over a great part of the central plain of England. The results of the Indian Survey are of great value as furnishing a broad outline of the stratigraphical features of the peninsula, but there will be work enough and to spare for both amateur and professional for many years to come before that outline is moderately filled in detail.

very considerable. The
the greater part widely-
general physiognomy of
far the most important part of the author's work is the excellent hypsometrical map which accompanies the book, and to which we referred a short time ago. Its scale is 1 : 30,000,000. The elevations are marked in eight different tints of brown, showing so many grades and altitudes from zero upwards. Thus at one glance we see the African continent rising as a rule from 0 to 600 metres in the northern half, while, in the southern half, elevations from 900-1200 metres are the rule. The greatest heights—those of 1500-3000 metres and more—are packed close together on the east side, between the southern end of the Red Sea and the Zambesi River, and only occur again in the extreme south-east (Natal) and far up in the north-west (Atlas). The text of the book is well written; the author's descriptions are always attractive, to the point, and free from all superfluous wordiness.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Struggle of Parts in the Organism

THE review of Dr. Roux's work on the "Struggle of Parts in the Organism" by Mr. Geo. J. Romanes which appears in your number of September 29 (p. 505) contains some passages which, I venture to think, are hardly consistent with the purpose to which the columns of NATURE are devoted. I understand that purpose to be the discussion of scientific facts and scientific laws, properly so called. I should be the last to deny that these facts and these laws may have, and indeed must have, their own ultimate bearing upon theology, whether natural or revealed. But it is not the purpose of a purely scientific journal to enter upon this discussion; it is one which cannot be there pursued without involving controversies alien to the spirit in which physical science ought to be studied and explained.

And if even temperate discussion upon the subject ought to be avoided in a purely scientific journal, still more ought there to be a scrupulous abstention from dogmatic utterances which are hostile to theological opinions, and which are unsupported by even the semblance of argument.

In the passages to which I refer Mr. Romanes asserts that to the whole "argument from design" in nature an "end has come"—as the result of Mr. Darwin's Theory of Evolution—that the "fountains of this great deep have been broken up by the power of one man," and that "never in the history of thought has a change been effected of a comparable magnitude and importance."

As an expression of the opinion of Mr. Romanes that the Darwinian theory ought to put an end to the "argument from design," this assertion may be allowed to pass. But as the assertion of a fact I venture to say that it has no foundation. There are many minds, including some of those most distinguished in science, who not only fail to see any contradiction between evolution and design, but who hold that the doctrine of evolution and the facts on which it is founded have supplied richer illustrations than were ever before accessible of the operations of design in nature.

I should be transgressing my own rule were I to defend this view in your columns. I shall therefore content myself with saying that no possible amount of discovery concerning the physical causes of natural phenomena can affect the argument that the combination and co-ordination of those causes which produce the "apparent" effects of purpose are really and truly what they seem to be—the work of Mind and Will.

Inveraray, October 4 ARGYLL.

Solar Chemistry

THE researches of Mr. Lockyer, and others, summarised by him in recent numbers of NATURE, have to a great extent complicated the aspect of this grand problem, which appeared so

Digitized by Google

simple to Stokes and Thomson in 1852, and to Stewart and Kirchhoff a few years later.

I wish to consider briefly, what are these new and puzzling complications of the solar problem; and whether we may not still preserve our belief in the existence of *essentially different* elementary atoms, which is the basis of the beautiful Vortex Theory. For it seems that to hazard (however *naturally*) such a step as is involved in assumed dissociation of the (so-called) elements, before we make certain that no less serious hypothesis will account for the observed facts, is contrary to the spirit of Newton's *Regulæ Philosophandi*.

The most prominent of these complications seem to be—

(1). The variations of the relative brightness, width, &c., of the lines in the spectrum of a particular substance, in dependence on the source and circumstances of its incandescence.

(2). The so-called "long" and "short" lines. (These, as will be seen, are probably a case of (1).)

(3). The fact that, in the spectra of sun-spots, *some* lines supposed to be due to a particular element indicate rapid motion of the glowing gas; while others, supposed due to the same element, give no such indication.

(4). The (at least apparent) coincidence of lines in the spectra of two or more elementary substances.

To these may be added:—

(5). The remarkable peculiarities of star-spectra; especially the paucity, and the breadth, of the lines in the spectra of *white* stars.

As regards (1), let us consider a sounding body with a large number of different modes of vibration, exposed to impacts either periodic or at least with an average period. The relative intensities of the various notes which it can give will obviously depend upon the period of the impacts. Now this is precisely the case of a particle (I use the word to avoid misconception) of a glowing gas. The average number of blows it receives will depend on (*a*) the number of particles per cubic inch (and also upon *whether there be another gas present or no*, a point of very great importance) and (*b*) the temperature, which is directly connected with the velocity of the particles.

Change the density, the temperature, the admixture with foreign substances, or any two, or all, of these; and the *average period of the battering* to which a particle is subjected may be so altered as to elicit from it *in any required ratios of relative intensity* the various simple rays it can give out.

It will readily be seen that this may account for all of the phenomena of classes (1) and (2) above.

(3) may be accounted for in many ways. I mention only one, as my object is merely to show that we are *not yet* compelled to accept dissociation of so-called elements even in its mildest form. Other modes of escape, though not quite so simple, present themselves.

What is seen in a sun-spot is the integral, as it were, of all that is taking place (as regards both radiation and absorption) in many thousand miles of solar atmosphere, containing the same substance under the most varied conditions. That portions in which certain lines of that substance are prominent over others may be at rest relatively to the observer along the line of sight; while others, in which (from different density, temperature, or admixture, as above explained) other lines are specially prominent, may have large relative velocities, is certain. This would at once account for these singular observations.

As to (5) we must remember that in a star spectrum we have, as it were, a *triple* integral. For we not only integrate through the depth of the atmosphere, but also over the whole surface of the star; spots, hurricanes, and rotation of the whole, included. This is equivalent to the *superposition* of innumerable separate spectra, no two of which may have *any one* individual line in the same place or of the same breadth, &c. Feeble lines may, in fact, entirely disappear under such treatment.

(4) If not due to want of dispersive power in the apparatus, this may be legitimately attributed to inevitable impurities. It is only in "tall talk" (or in advertisements) that any human preparation, elementary or not, can be spoken of as "*chemisch rein*." And we all know how faint a trace of impurity can be detected by the help of the spectroscope.

Even in the last resort, I see nothing to hinder the existence of exactly equal vibration-periods in two perfectly distinct vortex-atoms:—though their occurrence is extremely improbable.

If we could get an absolutely transparent gas; one, therefore, which could give no radiation under any circumstances; the study of the behaviour of a given quantity of hydrogen mixed with different proportions of it in a vessel of given size, and always to the same conditions of incandescence, would give invaluable information. G. F.

Replacing Flakes on Palæolithic Implements

THIS wonderful feat was first performed by my friend F. C. J. Spurrell of Dartford. On first thoughts the seems utterly impossible, and it is obvious that no flake possibly be replaced upon an implement unless one light exact spot where the instrument was made, and finds both ment and flakes in position. Mr. Spurrell so found his During the present summer I have discovered another Palæolithic floor, far removed from Mr. Spurrell's, and implements and flakes are exposed in a stratum perfectly turbed since they were gently covered up in Palæolithic with fine sand containing the shells of such freshwater as Unio, Cyrenia, and Bythinia. For obvious reasons chief one of which is that my work would be totally stop I mentioned the locality—I will content myself with stating the position is nearly a mile from any river, and the floor feet above the level of the nearest stream; above the floor thick deposit of fine stratified sand, and above that loam this Palæolithic floor I have found several implements large number of flakes, and on one of the finest implements an example 6 inches long, 3½ inches wide, and weighing I have been able to replace two flakes, one 2½ inches long other 2 inches in exact position; the flakes slightly over each other on the implement, and both have been struck the edge of the implement at right angles across its face. implement and flakes were close together, and with them found a hammer-stone of flint with a distinctly battered abraded edge. Mr. Spurrell replaced many flakes on implement, but the implement itself was a spoilt one example. My implement, on the contrary, is an unusually one, large, heavy, and perfect. Both the implement and show a little of the original grey crust of the flint from the instrument was made, and this peculiar grey colour led to attempt the replacement of the flakes with the above tioned successful result. One flake has a slightly uneven in some instances considered a proof of use—the second quite sharp. I shall exhibit this implement, with other ments, flakes, &c., from the same place, at an early meeting the Anthropological Institute. WORTHINGTON G. SMITH

Integrating Anemometer

PERHAPS the following brief description of the integr devised by me will suffice to establish its near kinship with Wilson's (NATURE, vol. xxiv. pp. 467 and 557):—A roller a spherical edge is made to revolve with a velocity propor to that of the wind as recorded on an anemogram. The presses on a plane table carried by two mutually perpendi pairs of rails in planes parallel to that of the table. The of the pairs of rails is supported by a frame carried at extremity of a vertical shaft. The point of contact of the with the table lies in the prolongation of the axis of the The table can rotate with the shaft, but not independently a simple arrangement the shaft, and consequently the table caused to take up positions corresponding from moment moment with the direction of the wind record on the gram. A style concentric with the shaft presses lightly a compound sheet of tracing and carbonised paper attached the under side of the table. Arrangements are also for obtaining the sum of the movements of the table towards of the four cardinal points. If the roller be moved velocity proportional to that of the wind, whether directly cup-anemometer or by a mechanical translation of the given by such an instrument, while the table simultaneously assumes orientations corresponding to the direction of move of the air, the line drawn by the style will be a miniature of the path of an imaginary particle animated by the movements actually belonging to the masses of air which successively the anemometer at the given station during the selected per rigorously in accordance with the principle known as Lambert. But in order that the trace drawn as described should correctly represent the actual movements of the air, it is evident that the whole mass of the atmosphere must be supposed to move "parallel to itself," *i.e.* in such a manner that the

W. J. HERSCHEL

THE AUTUMN MEETING OF THE IRON AND STEEL INSTITUTE

AT the meeting of the above Institution, which has just taken place, several papers of scientific and practical interest were read and discussed. They may be broadly divided into two classes, viz. 1st, those relating to the production of iron and steel, from the ore, and the qualities of the material when produced; and 2nd, the various applications to which steel has been put in recent times. The latter class of papers, at the recent meeting, dealt principally with the use of steel in the manufacture of ordnance, small arms, projectiles, and gun-carriages, and the papers, some of which were of great interest, will be reserved for consideration in a separate notice. Amongst the papers dealing with the manufacture of steel we may notice specially a memoir by Herr Paul Kupelweiser of Witkowitz, in Austria, on recent progress attained in the use of the basic process at the works with which he is connected. This process, which has been frequently referred to in NATURE, seems—probably on account of the quality of the ores met with—to have been adopted more frequently in Continental steel works than in our own country, for according to Herr Kupelweiser's summary, no less than thirty works in France, Belgium, Germany, Austria, and Russia, have acquired licences under the Thomas patents, the greater number of these being already at work; while the remainder are adapting their old plant, or erecting new works with the view to its immediate introduction. The weak point of the process hitherto has undoubtedly been the want of durability in the refractory linings of the converters, and on this point the author states that, in spite of numerous trials with other materials, the works with which he is acquainted still use the materials originally proposed by Mr. Thomas, viz. either the basic bricks or the shrunk lime and tar mixture. At Witkowitz, however, a new material has been used containing a comparatively small percentage of silica, and the quality of the bricks manufactured from this has been found to be materially improved. Ground brick mixed with 5 to 10 per cent. of tar is also used at many works for lining as well as for repairs. Basic tuyères have been tried in many places, but are not commonly used; but the author states that magnesia obtained by precipitation from chloride of magnesia by milk of lime appears, from experiments made on a small scale, to be a promising material for making tuyères. As regards the quality of the steel he makes the following remarkable statement:—"The basic process, as regards the quality of its products, is not only completely equal to the acid process, but even, in my opinion, superior to the latter." As a specimen of the excellent quality of the mild steel manufactured at Witkowitz the author exhibited a locomotive boiler tube made of this material, which had been expanded cold by means of a tube expander from 9 to 17 millimetres, on an original diameter of 48 millimetres, equal to an extension of from 20 to 36 per cent. on the periphery of the material, without even splitting at the line of weld.

Another paper of great interest to foreign manufacturers was Prof. Tünner's memoir "On the Use of Lignite or Brown Coal in the Blast Furnace." It is well known that the Austro-Hungarian Empire contains immense deposits of this fuel. It would be difficult to over-estimate the benefit which would accrue to the iron industry of Austria if this abundant and inexpensive fuel could be used successfully in the blast-furnace. All the experiments made in this direction till last year were of a more or less isolated and unsatisfactory character. In June, 1880, however, the "Mining and Metallurgical Association of Styria and Carinthia" appointed a committee to investigate the subject afresh. This committee has not yet reported, or indeed concluded its labours, but it is satisfactory to learn that it is fully acknowledged that there is no theoretical difficulty in the way of smelting

Digitized by Google

iron with raw or coked brown coal, and that the practical difficulties have been partly solved: for we learn that at Kalan a blast-furnace was for a time worked with a mixture of from 25 to 75 per cent. of brown coal, and 25 to 75 per cent. of coke. The great difficulty in the utilisation of this fuel lies in the fact that, owing to the high percentage of contained water, the raw coal is liable, when heated, to splinter up into small pieces, somewhat similarly to anthracite, and the coke formed of it is also very small and tender. It is, however, satisfactory to learn from Prof. Tunner that these difficulties may be in a measure obviated by the use of a strong blast, and especially constructed furnaces. The chief difficulty arises in continuing the operation when sponge-iron is produced; but it is suggested that the reduction might be completed from this stage in a small furnace, such as a Siemens furnace with coked fuel.

The results of the further labours of the Committee will be awaited with great interest.

Mr. G. J. Snelus of Workington contributes a paper on the Distribution of the Elements in Steel Ingots. It was till quite lately taken for granted that the steel plates, &c., produced from ingots were not only mechanically, but chemically homogeneous. When the disastrous failure of the boiler plates of the *Livadia* took place, this subject, amongst many others, was minutely investigated, and samples of different portions of the plates were submitted to chemical analysis, with the startling result that the proportions of carbon, manganese, phosphorus, and sulphur were found to vary greatly. At the spring meeting of the Institute Mr. Stubbs announced, during a discussion, that he had discovered that during the solidification of the ingots a redistribution of the elements took place, the carbon, sulphur, and phosphorus going to that part which remained fluid the longest. Mr. Snelus has now by experiment confirmed this statement so far as large ingots are concerned. This fact is brought out most clearly in the following table, which gives the analysis of carbon, sulphur, and phosphorus, of six samples taken from a slice 21 inches below the top of an ingot, measuring 7 feet × 19" × 19", and a similar number from a slice 4 inches above the bottom; the number in each case being taken from the outside, number 6 from the centre, and the remaining numbers from intermediate positions:—

	Top.			Bottom.		
No.	C. carb.	Sulphur.	Phosph.	No.	C. carb.	Sulphur.	Phosph.
1.	·44	·032	·044	1.	·44	·048	·060
2.	·54	·048	·060	2.	·42	·056	·062
3.	·57	·080	·086	3.	·41	·048	·054
4.	·61	·096	·097	4.	·40	·048	·054
5.	·68	·120	·111	5.	·38	·048	·058
6.	·77	·187	·142	6.	·37	·044	·052

In examining smaller ingots, however, Mr. Snelus found that the metal was practically homogeneous, and consequently the want of uniformity in the *Livadia's* boiler plates cannot be accounted for in this way, seeing that they were produced from relatively small ingots.

Mr. Edward Richards gave an account of a series of experiments on the strength of samples of mild steel. The specimens were tested both for ordinary tensile strength, and also for the tensile strength after the samples had been submitted to long-continued tensile and compressive strains approaching the elastic limit to torsional strains, and to long-continued strains below the elastic limit. He also made experiments on the strength of samples of plates which had been perforated. The results are of great interest, and will well repay careful study, though they are too voluminous to be reprinted here. We may however notice that in one sense these experiments go to support the much-combated opinion held by Dr. Siemens, that any mechanical treatment to which mild steel is subjected, has invariably the effect of increase of strength.

THE "QUARTERLY REVIEW" ON EARTHQUAKES

THE pages of the *Quarterly Review* contain for the very last place in which one would look for a new theory on an important scientific question. A perusal of an article in the July number of that on "Earthquakes: their Cause and Origin," leaves in grave doubt as to whether the author of it is seriously or is perpetrating a gigantic practical

The article professes to be a review of the and valuable works of Schmidt, Heim, and Earthquakes; but added to this list of books we have "Scepticism in Geology, and the by Verifier"! When we find that a considerable of the article is occupied with passages quoted last-mentioned book, in which the most absurd ceptions and misconstructions of the writings Darwin, Huxley, and others are embodied, scarcely forbear from leaving the task of hypothesis concerning earthquakes in order to in conjectures as to the relations which exist between "Verifier" and the author of the question.

Ignoring the whole body of facts which has accumulated by seismologists concerning the direction, and velocity of earthquake-waves, denies that the earthquake movements are wave and in his reasoning (if such it can be called) lessly confuses the vibration with the shock produced it. Dismissing with contempt the others on the subject, he proceeds to offer his than our old friend electricity, written with Some well-known examples of electrical discharge place from portions of the earth's surface are and it is then naively assumed that such discharges terrestrial electricity would produce the effects earthquake. The undulatory movements are be the result of a struggle of the electricity through cushions composed of soft, non-conducting materials, and the cracks and chasms opened in the surface.

The facts on which this extraordinary theory is jecture," as the author very properly terms it, be based are of two kinds. In the first place it occurred at the same time as earthquakes. In that peculiar atmospheric and electrical disturbances place Dr. Schmidt is quoted to prove that the earthquake shocks which he had studied in Greece had very mainly a course from north-east to south-west. author adds to this the fact that an earthquake occurring in the United States in the year 1870 took the same direction. He then asks triumphantly, "Is not the line of path habitually followed by storms a cause of earthquakes, our author then proceeds to make a number of suggestions which are rather sensational than practical. To the Atlantic Telegraphic Engineers he appeals to invent a method which shall ward off the electric currents and so earthquakes from their habitual haunts. Medical men are requested to examine the bodies of people killed during earthquakes in order to discover "lightning scars." And lastly, Sir William Thomson and other eminent electricians are asked to "direct their genius to that storehouse of unlimited energy already stored within the bosom of the earth," and to utilise it for our purposes.

This curious article may at least serve one useful purpose. Its author is evidently a man of some knowledge and considerable culture, and the errors into which he has fallen are examples of

at 30·370 inches, having thus
risen nearly two inches in little more than forty-eight hours.

On Saturday morning the centre of the storm had advanced fully 600 miles to eastward, being at the high daily average of 25 miles an hour, and was now near the south-west angle of Lake Wener in Sweden. Here the lowest barometer was about 28·600 inches, whilst at the same time to westward at Valentia pressure had risen to 30·220 inches, thus giving for the southern shores of the North Sea steep gradients for north-west winds, which, with the high seas they raised, proved very destructive to those coasts.

The anticyclone indicated by the high barometer following in the wake of the storm was accompanied with temperatures unusually low for the season during the night of Saturday-Sunday, when temperature fell to 27°·0 at Parsonstown and Nottingham; 29°·0 at Ardrossan; and 32°·0 at Leith, Shields, Cambridge, Oxford, and Mullaghmore. Snowfalls of some depth occurred in many districts, doing no little damage to green crops, and in later districts to grain crops still standing in the fields.

The lamentable destruction to fishing-vessels off the coast of Berwickshire was doubtless to no inconsiderable extent due to the deceptive character of the weather on Friday morning in cases where the barometer either is not consulted, or such a fall as an inch during the twelve hours immediately preceding, is discredited as a precautionary warning. In Midlothian, shortly after eight o'clock, the clouds broke up and the sun shone in a sky rapidly clearing of clouds. Soon, however, a change commenced, and within an hour, behind a low bank of darkish-looking clouds in the northern horizon, a long bank of ashy, leaden-hued, ominous clouds began to appear, and rose higher in the sky. In a brief space of time the whole of the sky was overcast, and a darkness quickly followed so great as to render gas necessary in reading the morning newspaper. It was remarked at the time that the darkness lasted three or four times longer than is usually the case with the darkness which is observed immediately to be followed by a complete change of wind. When it passed away, the wind had changed from south-west to north-north-east and the temperature fallen, and thereafter the wind gradually rose to a gale. On the other hand, off the Berwickshire coast the darkness was denser and more threatening, and almost simultaneously with its approach a hurricane broke out with a devouring energy which bore everything before it, and, explosively as it were, instantly rose to a height which, judging from actual facts related by the fishermen who escaped and the spectators on the shore, can perhaps only be paralleled in this country in recent years by the Edinburgh hurricane of January 24, 1868. On land many lives were lost in London and elsewhere, and in all parts of the country chimney-stacks, roofs, and walls were blown down, telegraph lines were wrecked, and tens of thousands of the finest trees were snapped asunder and levelled with the ground. When there has been time to collect the records of this storm, it will be found to have been one of the most destructive to life and property in these islands in the memory of the present generation.

THE INTERNATIONAL EXHIBITION AND CONGRESS OF ELECTRICITY AT PARIS[1]

IV.

AS we believe our readers will be interested in a fuller description of the arrangements for the telephonic hearing of the Opera than we have yet given, we extract the following from Nos. 50 and 51 of the new and popular French electrical journal, *La Lumière Électrique*, edited by Count Du Moncel. It is from the pen of the Count

[1] Continued from p. 564

Digitized by Google

himself, and is, we believe, the best account yet published. Our own additions are in square brackets.

One of the greatest successes of the Exhibition of Electricity is certainly the arrangement for the telephonic hearing of theatrical performances which has been organised by the Société Générale des Téléphones. By means of an electrical connection which has been established between the Opera, the Théâtre Français, and the Exhibition Palace, it has become possible to hear in the most complete manner the pieces played on our two principal dramatic stages. The singing of the Opera especially has a fairy-like effect, and all who have been so fortunate as to penetrate into the sanctuaries reserved for these hearings go away astonished and enchanted as if they had come from a dream of the Thousand and One Nights. The effect is in fact captivating; for the singing of the Opera is positively better heard in this way than in the Opera House itself; the words are more distinct, and the delicate turns of sound are better rendered, in consequence doubtless of the fact that the telephonic transmitters, being interposed between the actors and the orchestra, the instrumental music is to some extent sacrificed to the singing. It would scarcely be an exaggeration

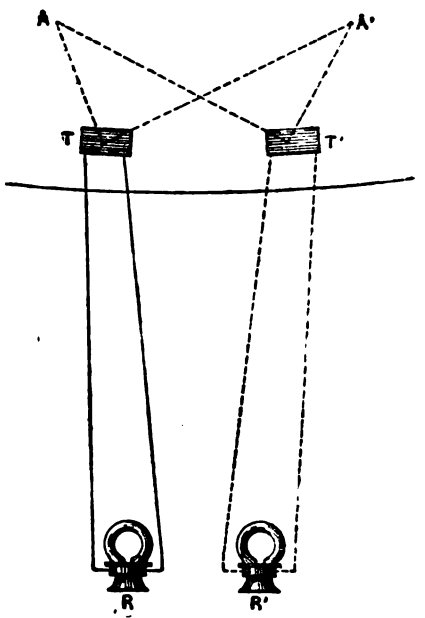

FIG. 1.—Stereoscopic combination of two transmitters.

to say that we hear too well, for the words of the prompter are heard with a distinctness which is somewhat distracting. In short the success is complete, and the Société des Téléphones, as well as M. Ader, who has superintended the arrangements, have a large claim on public gratitude.

The theatrical performances are to be heard not only in the four rooms allotted to the public, but also in a little boudoir off the so-called Salon de l'Impératrice, which is at some distance from the others. Here there are no external noises to distract, and it is possible to enjoy the charming melodies at one's ease.

The four public rooms, one of which is represented in Fig. 3, are covered on all sides with drapery to deaden external sounds, and the telephones are hung in pairs from wooden panels, of which there are twenty in each room. Chandeliers supporting lamps of Swan, Maxim, and Lane-Fox light each of these rooms, and the entrance to each is through a kind of pen which holds twenty persons in single file. The auditor has only to put the two telephones to his ears to hear the theatrical performance. On the table in the centre of the room there is a telephone for the use of the officials.

The connecting wires pass across the northern portion of the galleries of the Exhibition, and thence through sewer pipes to the Opera House and Théâtre Français where they abut on the stage of each of these theatres, and terminate in transmitters, which are in fact microphones with multiple contacts. Those which are employed are of the Ader system, and are the same as those which are used for the Telephonic Exchange of Paris, but with one slight modification to meet the exigencies of this special purpose. As is well known, the acting portion in these transmitters consists of a sort of gridiron composed of two fixed parallel bars of carbon loosely connected by means of six smaller cross-bars of the same material, whose ends are supported by resting in holes in the sides of the large bars, and are free to rattle about in them. This frame of carbons is attached in a horizontal position to the under side of a thin board of pine, which is the vibrating plate. [Sometimes the gridiron is double, so as to consist of three fixed bars, the middle one being connected to each of the others by five small bars or ten small bars in all). The terminals of the battery are in both cases connected with the two outside bars, and the current divides itself between the five small bars as it passes from each large bar to the next. An ordinary

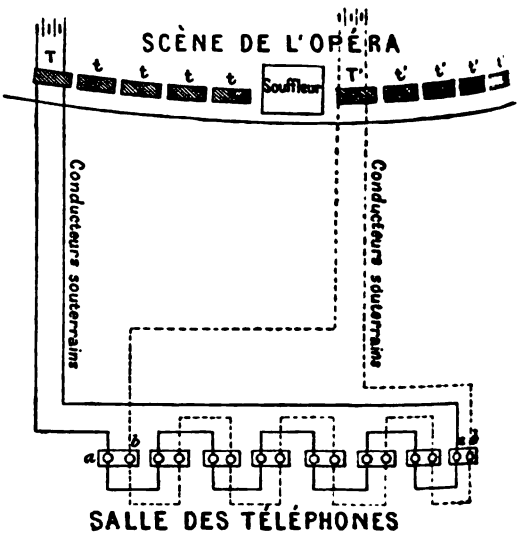

FIG. 2.—Connections between Opera and hearing-room.

five-barred gate, without the sloping tie, gives a good idea of the general form. It is one of the many forms which have been given to Crossley's microphonic transmitter, and is believed to be about on a par with many other forms.]

On account of the multiplicity and variety of sounds which it is capable of transmitting, it has been fixed on a leaden socket standing on four india-rubber feet, to deaden the effect of the vibrations of the floor of the stage. The necessity for such an arrangement is obvious in a theatre where the floor is continually being shaken by dancing.

At the Opera House there are ten transmitters of this kind disposed on both sides of the prompter's box along the edge of the stage. The arrangements suitable for any theatre vary according to the position and magnitude of its stage; and M. Ader informs us that he intends to double the number of transmitters at the Opera House, so as to render the sounds still more intense.

The receivers in the telephonic rooms of the Exhibition are the *téléphones à surexcitation* of M. Ader, which we have described more than once in this journal, and the arrangement of the batteries which work these multiple systems possesses no special feature. The batteries are

Digitized by Google

placed wherever there is room for them, generally underneath the stage; but as they would become too highly polarised if left in circuit during a whole representation, it is necessary to renew them every quarter of an hour, and for that purpose a commutator has been provided which allows the change to be made in a moment. This comutator consists of a board furnished with as many springplates as there are transmitters, and serves to keep up the connection between the transmitters and the batteries.

The greatest difficulty that has been met with has been how to render the transmitter more sensitive to the voices of singers than to the loud sounds emitted from the instruments of the orchestra, which would otherwise predominate. M. Ader has had to make a number of acoustic studies and trials on this point, which we cannot explain without going too much into detail, and has completely vanquished the difficulty; we will, however, explain the means which M. Ader has employed to enable the auditor to follow to some extent the movements of the actors on the stage.

Everybody knows the stereoscope, which enables a person, by means of the superposed visual impressions of the two eyes, to see the stereoscopic images with their natural relief. M. Ader applies the same principle to the perception of sounds.

Suppose two microphonic transmitters, placed on the

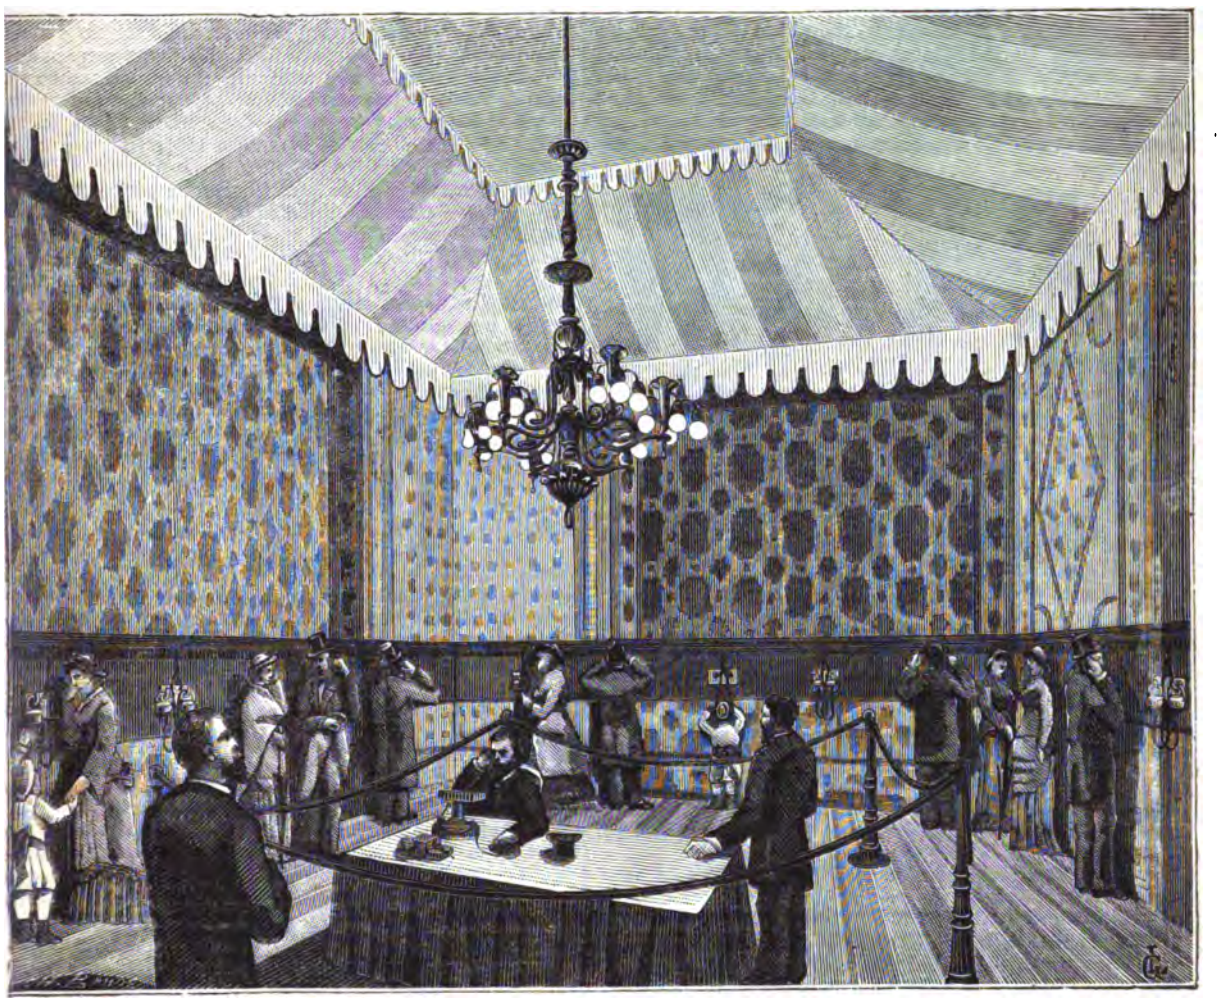

FIG. 3.—One of the hearing-rooms in the Exhibition.

tage at T and T′ (Fig. 1). Let one of them be connected ›y wires with the receiver R, and the other with the eceiver R′, these receivers being applied to the two ears f the auditor, and suppose an actor to stand first at A nd then at A′. In the former position, as he is nearer to ıe transmitter T than to T′, his singing will be heard ›udest with the left ear; but when he is at A′ he is nearer › T′ than to T, and the right ear will receive the strongest npression. Thus as he goes from A to A′ the definite ensation which the auditor will receive will be that of a iminution of loudness in the left and an increase of ›udness in the right ear, which is the same as the sensaon which we experience when a person who is speaking walks from our left to our right. The same principle will apply to a number of actors crossing one another on the stage. Fig. 2 explains how this idea has been carried out at the Opera House.

We have already stated that there are five transmitters on each side of the prompter's box [marked *souffleur* in the figure] along the edge of the stage. Each of these transmitters has its own separate circuit, and consequently its own separate underground cable. On arriving at the hearing room, the cables terminate each in eight receivers, but always in such a manner that to each auditor the effects are very different for his two ears. Fig. 2 shows the course of the circuits for two trans-

Digitized by Google

mitters, and the circuits for the others are arranged on the same plan. A little study of this figure is enough to show that in each pair of telephones in the receiving room the left one corresponds to the transmitters on the left side of the stage, and the right one to the transmitters on the right side. All the left-hand telephones are in one circuit, and all the right-hand ones in the other. This arrangement, which is clearly shown in the figure, is very ingenious, and though a simpler arrangement with a smaller number of circuits could have been employed, the additional expense involved in having so many circuits was not allowed to stand in the way, as it was necessary in order to make forty-two pairs of telephones work properly; and even this number is not sufficient to satisfy the public curiosity.

These brilliant experiments show that there was no exaggeration in the statements which were published soon after the invention of the telephone, to the effect that concerts and sermons had been heard at great distances. It cannot now be said that we were too credulous when we announced in 1878 that the opera

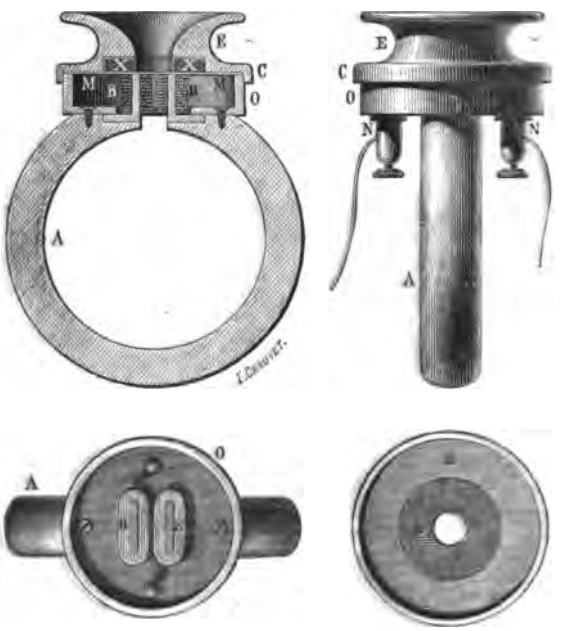

FIG. 4.—Ader's telephone *à surexcitation*.

"Don Pasquale" had been very well heard in the telephone at Bellinzona, and that none of the fine turns of this charming music had been lost. We believe indeed that the results then obtained were far inferior to those which we have now the opportunity of enjoying; and still more marvellous results in telephony have, we are informed, been quite recently obtained.

Fig. 3 represents one of the hearing rooms, namely, that which is lighted with Lane-Fox lamps. A mahogany wainscotting is carried round the walls at about the height of the ear, and on it are fixed twenty small wooden panels furnished with hooks to hang the telephones on. The telephones are connected with the underground conductors by means of flexible wire cords which come out of the wainscotting, so that nothing is easier than for the auditors to put the telephones to their ears. As the telephones are connected, eight in each series, with one and the same pair of microphonic transmitters, and the different pairs of transmitters occupy different positions on the stage, the effects are not the same for all the telephones. Those which are in connection with transmitters at the extreme right or left are more affected by the sounds of the loud instruments in the orchestra than those which are connected with the transmitters nearest the prompter; but these latter, on the other hand, are more affected by the prompter's voice.

To make the effects as equal as possible, M. Ader has so arranged the connections that the two transmitters which form one pair are in precisely opposite conditions; for instance, the transmitter at the extreme left is paired with the first to the right hand of the prompter, the second from the extreme left with the second to the right of the prompter, and so on. The best effect is obtained from the pair which occupy the middle places in the two sets. These differences give an obvious explanation of the different accounts given by different persons of the predominating sounds which they have heard, and explain why many of them, having heard in different parts of the same room, have not received the same impressions. Naturally enough they attribute the difference to the quality of the telephones, but though it is possible that some of these may be better than others, it is to the positions of the transmitters on the stage that the differences are chiefly attributable.

[The receiving instrument, which, as above stated, is the *telephone à surexcitation* of M. Ader (pronounced like the English name Adair), is very similar to the Gower-Bell receiver, having like it a steel horseshoe magnet which forms nearly a complete ring, and which, being coated with nickel, serves as the handle. Round the two soft iron pole-pieces of this magnet coils of very fine wire are wound, which are in circuit with the line wires, so that the currents from the transmitter at the sending-station pass through them. A thin circular plate of iron, fastened by its edges, is fixed at a very small distance from the pole-pieces, and serves as the vibrating diaphragm. The peculiarity of the Ader telephone is that a flat ring of soft iron is fixed at a little distance behind this vibrating plate; that is to say, on the side remote from the magnet, its office being to concentrate and intensify the force of the magnet upon the diaphragm. This is what is meant by *surexcitation*. The plate, in fact, is more strongly attracted by the magnet than it would be if this ring were absent. In Fig. 4 (which consists of three sections and one elevation of this telephone) A is the steel magnet, B B are the coils, M M is the vibrating diaphragm, X X the flat ring for intensifying the force of the magnet upon the diaphragm, O the resonance chamber, and E the trumpet-shaped opening which is applied to the ear.]

The following account of Rysselberghe's meteorograph was accidentally omitted from a previous article:—

One of the neatest specimens of electrical mechanism is the meteorograph of M. Van Rysselberghe, exhibited by the Royal Observatory of Brussels. It gives its records not only at the place of observation, but at one or more distant stations, and is now giving every night at Paris a record of the indications of the instruments at Brussels. Once every ten minutes it comes into action and registers one after the other the six following elements:—(1) temperature; (2) humidity; (3) water in rain-gauge: (4) direction of wind; (5) barometer; (6) velocity of wind. It also makes a mark about every half second due to the action of clockwork at the sending-station.

The registration is made by a diamond point on a thin plate of zinc which is bent round the surface of a revolving cylinder, and which is covered with lamp-black to make the marks more visible. This plate serves afterwards for printing any number of copies. There may be several of these cylinders at as many different stations, all recording simultaneously the indications furnished by any one station. The mode of action is as follows:—

Let us take for example the case of one of the thermometers. The thermometer-tube is vertical and open at the top. A long metallic probe smaller than the tube of the thermometer descends once in ten minutes with a

Digitized by Google

slow motion produced by clockwork. The probe, by touching the mercury, completes a circuit, through which a current is instantly transmitted from a local battery. The line-wire is included in this circuit, and a corresponding movement is produced in the diamond point of the receiving instrument. A local electro-magnet is also made by this current, and the arrangements are such that the current is thus diverted from the mercury at the instant after the probe has touched it, and there is consequently no spark when the probe leaves the mercury. The instantaneous current which thus passes is always from the probe to the mercury; in other words the mercury is the negative and the probe the positive terminal. If any moisture be present its oxygen goes to the probe (which is of platinum) and the hydrogen to the mercury, which thus, instead of oxidising, is kept always bright. Evidently the higher the mercury stands in the tube, the sooner will the contact be made, and thus the scale of equal parts before-mentioned gives the height of the mercury.

The diamond point makes a succession of short marks which (in virtue of a mechanical interruption) form a regular series up to the moment when the probe touches the mercury, after which they cease for several seconds. The cylinder revolves once in ten minutes, and the diamond point has at the same time a slow longitudinal motion (being mounted on a screw axle), so that the successive indications of the same thermometer form a nearly continuous curve (traced by points).

Thus by one line wire and one diamond point the curves for all the six instruments are drawn at a station which may be 200 or 300 miles distant. The value of such an instrument for furnishing the director of a central station with accurate data on which to base his weather-predictions speaks for itself; and as regards expense, all the expenses of photography and of reducing and engraving photographic traces are saved. It has been worked in Belgium over a wire of the length of 750 miles.

(*To be continued.*)

NOTES

THE Royal Institution Session will commence with a course of six lectures on astronomy, adapted to a juvenile audience, by Prof. R. S. Ball, F.R.S., Astronomer-Royal in Ireland. Dr. W. Huggins will give a discourse on Comets at the first Friday evening meeting, January 20, 1882.

THE International Commission for the next transit of Venus, established in Paris under the presidency of M. Dumas, has accomplished its work and published a series of instructions, which will appear in the next number of the *Comptes rendus* of the Academy of Sciences, and be sent to all astronomers and observatories. A complete scheme for international co-operation has been adopted.

AS No. 12 of the Bibliographical Contributions, edited by Mr. Justin Winsor of the Harvard University Library, we have List of the Publications of Harvard University and its Officers, 1870–80. It contains, for example, the publications of the Astronomical Observatory, the Bussey Institution, the Museum of Comparative Zoology, &c., followed by an alphabetical list of the officers (professors, &c.) of the University with their publications, and including such names as those of Agassiz, father and son, J. A. Allen, the ornithologist, F. P. Cooke, professor of chemistry, Asa Gray, H. A. Hagen, professor of entomology, E. C. Pickering, professor of astronomy, the late Benjamin Peirce, S. H. Scudder, N. S. Shaler, Trowbridge, professor of physics, and others.

THE experiments made at the Paris Opera in electric lighting have been successful for regulators. Not less than thirty-six Brush lamps illuminated the celebrated monumental staircase, with Werdermann in the circular gallery, and Jaspar in the buffet. Sixty-four Jablockhoff lights were disposed on the ceiling round the chandelier with success in spite of the numerous changes of colour. The incandescent light exhibitors—Swan, Maxim, and Edison—were not ready to act their part, and the opportunity was lost for them; a second will be given to-day.

A RUMOUR has been spread by the *Journal Officiel* that the Electrical Exhibition will be closed on the 1st of November. The impending resignation of M. Cochéry is stated to be at the bottom of this semi-official attempt. But it is certain no alteration will be made in the original date of closing, except to extend the time granted up to December 1.

THE death is announced, at the age of eighty-four years, of M. Dubrunfaut, a well-known French industrial chemist.

IT is stated that M. Hervé-Mangon, director of the Paris Conservatoire des Arts et Métiers, has decided to resign his post in order to devote himself more entirely to politics, he having been elected recently as *député* for the department of La Manche. Probably he will be succeeded by Col. Laussedat of the Polytechnic School.

PROF. HAECKEL has arrived at Vienna on his way to Ceylon.

IN connection with the Museum and Library, Queen's Road, Bristol, the following syllabus of a course of nine lectures, on literary and scientific subjects, to be delivered during the winter, 1881–82, has been issued:—October 31, 1881, Clements R. Markham, C.B., F.R.S., Sec. R.G.S., the Basque Provinces of Spain; November 14, Prof. W. J. Sola, M.A., F.R.S.E., F.G.S., the Natural History of Volcanoes; November 28, Prof. S. P. Thompson, B.A., D.Sc., F.R.A.S., Electric Storage and Lighting; December 12, Prof. William Ramsay, Ph.D., F.C.S., Improvements in Iron and Steel Manufacture; January 23, 1882, Prof. Bentley, F.L.S., Epiphytic and Parasitic Plants, with some observations on the Life of other Plants; February 6, Ven. Archdeacon Norris, B.D., Canon of Bristol, Redcliffe Church: its Architecture and History; February 20, J. E. H. Gordon, B.A., the Leyden Jar; March 6, W. Saville Kent, Infusoria; March 20, Rev. A. H. Sayce, M.A., the Land of the Phœnicians.

LIEUT. FRIEDRICH WILL will shortly undertake a thorough zoological-entomological investigation of the provinces of Bahia, Pernambuco, and Piauhy; he is sent by the Entomological Society of Stettin, the president of which is Dr. C. A. Dohrn.

WE have received parts 1 and 2 of the first volume of the *Transactions* of the Seismological Society of Japan, containing an address on Seismic Science by Prof. Milne, together with papers by Messrs. Ewing, Wagner, and Gray, on various seismometric and seismographic instruments, and by Mr. Mendenhall on a determination of the Acceleration of Gravity at Tokio. The Society is to be congratulated on the numerous proofs of activity which it has already shown, and on the very valuable scientific work it is doing in this rather neglected branch of study.

A USEFUL paper by Mr. W. J. Harrison, Science Demonstrator for the Birmingham School Board, on the Teaching of Science in Public Elementary Schools, has been issued by him in a separate form. He resumes all the reasons for science-teaching in schools in a clear and forcible manner, and gives some hints that might be of service to science teachers. In Birmingham, we believe, they are now endeavouring to obtain money for science scholarships, by which boys of merit will pass from the Board Schools to the great Foundation School there (King Edward's Grammar School), then to the Mason College,

Digitized by Google

and perhaps subsequently to some university. There are now 2000 children and 200 pupil teachers under science instruction in Birmingham, and the results so far have been most encouraging.

MAJOR-GENERAL MAITLAND, writing to the *Times* in connection with the Bordeaux Phylloxera Congress, makes a suggestion which appears quite worthy of attention. He believes that all the remedies hitherto applied or proposed are open to the reproach to which all empiric treatment of disease is obnoxious—viz. the attacking of a symptom instead of the essential root of the disease, and thus betraying a want of right apprehension of its true origin. "This, in my humble view," General Maitland says, "is to be attributed to exhaustion of the vitality of the plant, induced by unduly and unnaturally overtasking its productive powers. In this respect the phylloxera of the French vineyards bears a close analogy to the red spider of the Indian tea garden, to the leaf-worm of the Indian, American, and other cotton fields, and, in short, to parasitic growth wherever proving fatally destructive throughout the vegetable kingdom. The mode in which this law of nature, as it may be termed, operates, may be understood by reference to the physiological paradox, 'Life dies; death lives.' Wherever the vitality of a plant is abnormally diminished by over-plucking, over-pruning, and unceasing inexorable demands to produce more, more, when nature demands rest and repose to recruit exhaustion, the sap, the plant's life-blood, becomes poor, sluggish, and enfeebled. Parasitic life is then evolved, and preys upon the little remaining life that injudicious culture has left the plant. If the above view in regard to the origin of phylloxera be accepted as an approximation to the truth, the remedy would seem to be self-indicated—repose. Give the vineyards rest."

AN extraordinary report of four large expeditions for Africa being organised in Brussels, was lately given in the *Pall Mall Gazette*, and has this week been reproduced by the *Daily News*. There is, however, absolutely no foundation for the statement.

THE *Colonies and India* states that the unusual spectacle of snow was seen on Table Mountain on August 16. Such an occurrence has been recorded only once since 1813, viz. in 1878.

THE first list of the honorary council of the International Electric Exhibition which is to be held at the Crystal Palace, comprises the following names of well-known men of science:—Mr. James Abernethy, President Institute Civil Engineers; Prof. W. G. Adams, F.R.S., Sir James Anderson, Prof. Ayrton, F.R.S., Sir Henry Cole, K.C.B., Mr. William Crookes, F.R.S., Capt. Douglas Galton, C.B., F.R.S., Dr. Gladstone, F.R.S., Col. Gouraud, Sir John Hawkshaw, C.E., F.R.S., Dr. J. Hopkinson, F.R.S., Prof. Fleeming Jenkin, F.R.S., Sir E. J. Reed, C.B., M.P., Mr. B. Samuelson, M.P., Dr. C. W. Siemens, F.R.S., Mr. W. Spottiswoode, President Royal Society. The following gentlemen will be the chief officers for the Exhibition: Manager, Major S. Flood Page; secretary, Mr. W. Gardiner; superintendent, Mr. P. L. Simmonds; assistant engineer for Exhibition, Mr. R. Applegarth, C.E.; clerk of works, Mr. W. Carr.

THE Programme of the Technological Examinations of the City and Guilds Institute for 1881-2 contains several new subjects and arrangements—improvements on previous programmes. The examination papers set for 1881 are interesting.

WE notice in the Russian journal, *Old and New Russia*, an interesting paper on M. Tyaghin's wintering at Novaya Zemlya, on hunting in that land, together with a good sketch of the bird life in the neighbourhood of the wintering place.

DR. GOBI, who has investigated during many years the flora of the White Sea, has published his researches in a separate work in Russian.

WE notice in a paper published in the *Annals* of the Spanish Society of Natural History (vol. x. 1881), that Don Fr. Quiroga observes that the numerous implements in Spanish museums which are usually described as nephrite are mostly made of fibrolite, this name having been given by Count de Bournon to a variety of sillimanite. Out of 115 hatchets which were considered as nephrite, and were found mostly during a geological survey of the provinces of Guadalajara and Cuenca only one was of nephrite, whilst 111 were of fibrolite and five of jadite. The fibrolite is often found among the mica-slates of the provinces of Madrid and Guadalajara.

THE same volume of the *Annals* contains a paper, by Don S. Calderon of Arana, on the evolution of the earth.

A STRIKING instance of the activity of man in destroying forests may be shown by the following figures, which we find in M. Olshevsky's paper in the last issue of the *Izvestia* of the Russian Geographical Society. After having taken into consideration the surveys which were made in the province of Ufa before 1841, and the recent distribution of forests in that province, M. Olshevsky shows that the area of forests, which formerly was about 17,577,000 acres, has now diminished by at least 3,500,000 acres; although the population is still very sparse, that is, less than three souls per square mile, and it was yet less some time ago.

THE well-known publishing firm of A. Hartleben (Vienna, Pesth, and Leipzig) have recently published a little work by Heinrich von Littrow, "Carl Weyprecht, der österreichische Nordpolfahrer." It contains many characteristic reminiscences as well as letters of the late discoverer of Franz-Josef Land. It is a fitting and touching literary monument to a brave, energetic, highly-cultivated, kind, and modest man of science, whose noble career was unfortunately cut short so prematurely.

Auf der Höhe is the title of a new international review, edited by Leopold v. Sacher-Masoch, and published at Leipzig by Gressner and Schramm (London: Dulau). The first number (October) contains several interesting articles, though none of them scientific; among the list of contributors, however, we notice the names of several Continental men of science.

DR. KING'S report on the Government Cinchona Plantations in British Sikkim for the year ending March last, shows a continued and highly satisfactory progress—a progress that has been made not only in the extended cultivation of well-known and established species, but also in the propagation of valuable and rarer kinds. Most satisfactory results are recorded of the species known as *Cinchona Ledgeriana*, one of the varieties of *Calisaya*, which, as Dr. King says, is surpassingly rich in quinine, and which has derived its name from Mr. Ledger, a collector who brought the seed from South America. Regarding another valuable kind, namely, the plant yielding the Carthagena or Columbian bark, which is largely imported to this country from the northern part of South America, and of which four plants were sent to the Government Plantations from Kew in January 1880, Dr. King says, "They arrived in good condition and during the year they were increased largely by cuttings. Propagation went on most favourably for some time, but later on in the year the young plants were severely attacked by the pest only too well known to gardeners as 'thrips.' The usual treatment was applied with vigour, but in spite of this, when the year ended the six original plants had been increased only to eight rooted plants and ninety partially rooted cuttings." Dr. King however, further says that "every effort will continue to be made to increase the stock of this interesting species." But the general condition of the plantation and the financial results are reported as satisfactory, and the results as gathered from the quinologist's report, which is appended, are also satisfactory inasmuch as they show an increased manufacture of febrine and also an increased demand. Dr. King and his co-workers

Digitized by Google

are to be congratulated on the continued successful results of their labours.

DR. OBST, the director of the Ethnographical Museum at Leipzig, after attending the Archæological Congress at Tiflis, intended to make an exploring tour in the Caucasus, Armenia, and Asia Minor, and then to return to Saxony *viâ* Constantinople and Athens.

A STRANGE phenomenon was recently observed at Emerson, near Lake Winnipeg. A dark cloud formed of myriads of winged black ants passed over the place from east to west. When it descended the ground over a large area was covered an inch deep with the insects.

MAUNA LOA (Hawaii) is again active, and the lava threatens the port of Hilo, situated on the east side of the island.

IN a letter which we have received from Mr. G. H. Kinahan he disavows the suggestion imputed to him (NATURE, vol. xxiv. p. 471) that Laurentian rocks occur in Co. Tyrone.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus* ♀), a Bonnet Monkey (*Macacus radiatus* ♀) from India, presented by Mr. G. E. Jarvis; a Vervet Monkey (*Cercopithecus lalandii* ♂) from South Africa, presented by Mrs. Brassey; two Leopards (*Felis pardus*) from Ceylon, presented by Lieut.-Col. J. S. Armitage, F.Z.S.; a Mesopotamian Fallow Deer (*Cervus mesopotamicus* ♀), two Beatrix Antelopes (*Oryx beatrix* ♀ ♀), two Arabian Gazelles (*Gazella arabica* ♂ ♀) from Muscat, presented by the Lord Lilford, F.Z.S.; a Naked-footed Owlet (*Athene noctua*), European, presented by Mr. R. J. Marlton; a Common Kestrel (*Tinnunculus alaudarius*), a Common Hare (*Lepus europæus*), European, presented by Mr. W. K. Stanley; a Paradise Whydah Bird (*Vidua paradisea*) from West Africa, presented by Mr. Bowyer Bower; two Bonnet Monkeys (*Macacus radiatus*) from India, a Bell's Cinixys (*Cinixys belliana*) from East Africa, deposited; an Osprey (*Pandion haliaetus*), European, purchased; a Hardwicke's Hemigale (*Hemigalea hardwickii*) from Borneo, received on approval.

OUR ASTRONOMICAL COLUMN

THE SATELLITE OF NEPTUNE.—We subjoin such a table as was suggested by Prof. Newcomb for indicating with little trouble the approximate position of the satellite of Neptune, at any time about the approaching opposition. The argument *u* has the same significance as in Newcomb's Tables:—

Argument *u*.			Angle of Position.			Distance.
°		°	°		°	″
0 ...	180	...	73·3 ...	253·3	...	11·4

		6	15·31
		12	30·63

From which figures *u* may be interpolated for any hour required. When *u* is found in the second column of the table, the angle of position is to be taken from the second column.

COMET 1881 *f* (DENNING, OCTOBER 3).—The comet discovered by Mr. W. F. Denning of Bristol during the night of the 3rd inst. has been observed at Marseilles by M. Coggia, and at Lord Crawford's Observatory at Dunecht. Elements calculated by Dr. Copeland and Mr. Lohse upon Dunecht observations on October 9, 10, and 12, are as follows:—

Perihelion passage 1881, September 12·0943, Greenwich M.T.

Longitude of perihelion	22 6 9	M. Eq. 1881·0
Ascending node	72 47 45	
Inclination	7 45 12	
Log. perihelion distance	9·859822	

Motion—direct.

Hence it is found that this comet, like that discovered by Mr. Barnard on September 19, is receding both from the sun and the earth. As remarked in Lord Crawford's Circular, No. 33, the elements bear some resemblance to those of the fourth comet of 1819, detected by Blanpain at Marseilles, which was certainly moving in an elliptical orbit of very limited dimensions. This circumstance alone attaches a particular interest to Mr. Denning's comet, and makes it of importance that it should be accurately observed for position as long as practicable.

CERASKI'S VARIABLE—U CEPHEI.—The following Greenwich times of minima depend upon Mr. Knott's observation on the 2nd inst. with the period 2ᵈ·49280:—

	h. m.		h. m.		h. m.
Oct. 22 ...	10 24	Nov. 11 ...	9 1	Dec. 1 ...	7 39
27 ...	10 4	16 ...	8 41	6 ...	7 18
Nov. 1 ...	9 43	21 ..	8 20	11 ...	6 57
6 ...	9 22	26 ...	7 59	16 ...	6 37

BIOLOGICAL NOTES

THE HYPOPHYSIS IN ASCIDIANS.—In a second paper to the Belgian Academy on this subject (*Bull.* No. 6) M. Julin describes the quite special arrangement of the "hypophysary gland" in *Phallusia mamillata*. Besides the principal excretory duct existing in all Ascidians, and here considerably reduced, there are a large number of orifices by which the glandular tubes pour their product of secretion into the peribranchial cavity, of which the cloaca forms the median part, which receives all the products and residues of the organism, to be cast out. Hence the products of the hypophysis in this species are probably also excrementitial, and the gland is physiologically the kidney of the animal. If it be so with *P. mamillata* it is likely to be the same with the other Tunicata; and though, in most, the hypophysis opens into the mouth, one cannot infer that the product is to be utilised in the alimentary canal. From the morphological point of view it is noteworthy that in glands properly so-called, arising from an epidermic or epithelial invagination, the product of secretion is generally eliminated by a single orifice, and that the only exceptions occur in the category of urinary apparatus (Cestodes, Trematodes, &c.).

THE CORALS OF SINGAPORE.—We learn from a paper (*Proc.* of Berne Nat. History Society) by Prof. Studer, on the Corals of Singapore, that there are no less than 122 species known from this locality. Of these fifty-one species are special to the locality, whilst the others inhabit the seas of New Guinea, of the New Britannic Archipelago, of the Solomon Islands, and reach as far as Fiji, some few extending as far as Tahiti. At the same time the Singapore corals yield very few species in common with the Red Sea, the Seychelles, and Mauritius, and these are Fungidæ, but no Madreporaceæ. Thus it may be established that the coral fauna of the Indian Ocean must be divided into two distinct regions—a western and an eastern, the latter extending far to the east into the Pacific. These two

Digitized by Google

regions are divided by deep sea and by coast-lines, which, as the eastern and southern coasts of India, do not afford the necessary conditions for the development of corals, whilst the extension to the east is much facilitated by low grounds and favourable coast-lines. Nevertheless, however different as to the species which inhabit them, both regions have a close likeness as to certain species, and both might be considered as having formed a single region, probably at the time when the great plateau of the Sunda Islands was a continuation of the continent, and when Madagascar and Ceylon were in close connection. As to the inhabitants of greater depths and of colder water—as the Gorgonids, the Anthozoa, and the Primnoids—the same species are widely spread throughout the Pacific and the Indian Ocean, showing thus that the differentiation of shallow-water forms goes on more rapidly than that of the deep-water ones.

A Chemical Difference between Living and Dead Protoplasm.—From various experiments (chiefly with protoplasm of plants, also with Infusoria) Herren Loew and Bokorny find (*Pflüger's Arch.*) that living protoplasm possesses in an eminent degree the property of reducing the noble metals from solutions, and that this property is lost when death occurs. "It may well be inferred," say the authors, "that the mysterious phenomenon denoted by the name of 'Life' depends essentially on these plain these 'groups in motion,' these springs of life phenomena, as aldehyde groups, but would by no means exclude some different and better mode of explanation."

Rattlesnake Poison.—Dr. Lacerda Filho has published the results of his experiments on the poison of the rattlesnake (*Crotalus horridus*) in the *Archivos do Museu nacional do Rio de Janeiro*, iii. 1. The poison of *Crotalus horridus* acts upon the blood by destroying the red-blood corpuscles, and by changing the physical and chemical quality of the plasma. 2. The poison contains some mobile bodies similar to the micrococcus of putrefaction. 3. The blood of an animal killed by the snake's bite, when inoculated to another animal of the same size and species, causes the death of the latter within a few hours, under the same symptoms and the same changes of the blood. 4. The poison can be dried and preserved for a long time without losing its specific quality. 5. Alcohol is the best antidote to the poison of *Crotalus horridus* known until now.

The Spermogonia of Aecidiomycetes.—According to recent observations by Prof. Rathay (Vienna Acad. *Anz.*) the spermogonia of Uredineæ or Aecidio mycetes may discharge their contents without the action of external moisture, of rain or dew (the only way, as apparently supposed by A. de Bary). The process may occur in dry and hot sunny weather, and as follows:—These spermogonia produce in their interior not only mucilage and spermatia, but also sugar. In virtue of the latter they separate water by "osmotic action," and this water causes the inclosed mucilage to swell, and thereby afford exit from the cavity. The author's observations were made upon the spermogonia of *Cæoma sporangium conicum* and *Puccinia anemones*.

Pelagic Fauna of Gulf Stream.—Alexander Agassiz gives an interesting account of his explorations of the floating fauna of the Gulf Stream in the vicinity of the Tortugas. The party remained at this station for some five weeks, being allowed to select quarters at Fort Jefferson. Unfortunately during the greater part of their stay the strong northerly winds interfered greatly with the surface fauna. Had the south-easterly winds prevailed the fauna would have been driven against the Tortugas. The few favourable days showed, however, a wealth of pelagic animals which had been hardly anticipated, and which proved how excellent a station this would be to investigate the fauna from. It also has the immense advantage of supplying the naturalist, and at his very door, with not only the common species of reef-building corals, but with the varied invertebrate fauna to be found in such places. Leaving a full enumeration of the species for another occasion, in the letter we now notice (*Bulletin* of the Mus. Comp. Zoology, vol. ix. No. 3) A. Agassiz mentions in a general way the presence of a couple of species of Pleroldes, of Phyllirhoe, of several Appendicularia, of a small Pyrosoma, of a Doliolum, two species of Salpa, and half a dozen species of Pteropods. The number of pelagic foraminifera was greatly disappointing; not once was a species of Globigerina met with, and the Radiolarians appear to have also been scanty. A list of the Ctenophoræ, Discophoræ, Siphonophoræ, and Hydroids met with is appended by Mr. Fewkes. Many of the species are indicated as new.

Retarded Development in Insects.—In a paper read before the American Association, Prof. C. V. Riley, at the recent meeting of the Association, the author records several interesting cases of retarded development in insects, whether as summer eggs in the case of a certain portion of a given brood of caterpillars, or in the hatching of eggs. One of the most remarkable cases of the latter is which he calls attention is the hatching this year of the eggs of the Rocky Mountain Locust or Western Grasshopper (*Caloptenus spretus*) that were laid in 1876 around the Agricultural College at Manhattan, Kans. These eggs were buried some inches below the surface in the fall of 1876 in grading the ground around the chemical laboratory, the superincumbent material being clay, old mortar, and bits of stone, and a plank being laid above this. In removing and regrading the ground in spring Mr. J. D. Graham noticed that the eggs looked sound and fresh, and they readily hatched upon exposure to atmospheric influences, the species being determined by Prof. Riley from specimens submitted by Mr. Graham. Remarkable as the fact is, there can be no question as to their accuracy, as the eggs actually remained unhatched during nearly four years. The significant question, How much longer than is their wont; and this question could, under favouring conditions of dryness and moderate temperature, retain their vitality and power of hatching? Putting all the facts together, Prof. Riley concludes that we are at present absolutely incapable of offering any satisfactory explanation of the causes which induce exceptional retardation in development among insects. The eggs of Crustaceans, as those of *Apus* or *Cypris*, are known to have the power of resisting drought for six, ten, or more years without losing vitality, while in many cases they seem actually to require a certain amount of desiccation before they will hatch. Yet the fact remains that different species act differently in this respect. In short, nothing is more patent to the observing naturalist than that species and even individuals of the same species, or the progeny of one and the same individual, act very differently under like external conditions of existence: in other words, that temperature, moisture, food, &c., influence them differently. Hence, as has been pointed out by Semper to be the case with other animals, so it is with insects, changes in the external conditions of existence will not affect the fauna as a whole equally, but will act on individuals. Such conditions may and does, in the case of exceptional seasons, prove beneficial to the species by preserving the exceptional individuals that display the power to resist the unusual change, but we shall find ourselves baffled when we come to seek an explanation of the cause or causes of such retardation, unless we accept certain principles of evolution. In the case of the property of organisms to vary, and in the complex phenomena of heredity, we may find a partial explanation of the fact, or the exceptional tendency in the present may be looked upon as a manifestation through atavism of traits which in the past have been more commonly possessed and more essential to the species.

PHYSICAL NOTES

A singular case of the production of sound by natural causes is recorded by M. Reuleaux (*Prov.* of the Nat. Hist. Soc. Prussian Rhineland and Westphalia). He observed it while walking in the Rödertbacherthal, near the highest point of the Eifel province. The ground is, in the main, gently undulating and densely wooded. The valley, spacious on the eastern side, narrows rapidly at one part to a sort of pass, through which for about one kilometre, the Rödertbach flows westwards. A south-west wind was blowing, and M. Reuleaux, coming down the hillside from the east, heard what appeared to be the sound of a fine deep-toned bell in rapid succession. There was no such bell in the neighbourhood, and some other cause was sought. heard satisfied him that the effects were of natural origin. The were heard growing in force to a maximum, then dying away they were like those of organ-pipes at first, but their quality came to resemble that of a harp or violin. At the end of the pass, whence the sounds seemed to radiate, there was a strong agitation in the air, and a mixture of sounds, some of which abruptly stopped. M. Reuleaux supposes bodies of ice to have and the sound to have been carried along from them by the and the inner air at the mouth of such caves [illegible] lations. There was [illegible] difference of temperature [illegible]

Digitized by Google

the higher and the lower parts of the valley, and this is regarded as an important factor in the case; the cold air above pressing on the warm below, and closing the pass to a sort of tube. The wind seemed to be active only in the lower parts.

WITH the aid of delicate apparatus of recent invention Herr Grunmach (*Wied. Ann.* No. 9) has investigated the electromagnetic rotation of the plane of polarisation of radiant heat in solid and liquid substances (flint glass, plate glass, sulphide of carbon, oil of turpentine, distilled water, and alcohol). His finding is as follows:—1. In solid as well as in liquid diathermanous bodies there is such rotation, and always in the direction in which the current flows through the spiral or circulates round the magnetic core. 2. The amount of this rotation is, *cæteris paribus*, very different for different substances; the rotation is greater the greater the index of refraction of the substance. 3. With direct action of a galvanic current conducted round the diathermanous body, the amount of the rotation is proportional to the intensity of the current. 4. In a diathermanous body placed between the poles of an electromagnet, the amount of rotation is proportional to the magnetic force acting on the body. 5. The amount of rotation increases with the length of the substance traversed by the rays; but the relation between these two quantities could not be numerically determined.

EXPERIMENTS on heat-conduction have been lately made by M. Christiansen of Copenhagen (*Wied. Ann.* No. 9), by the following simple method:—Three round copper plates are placed one above another, separated by small pieces of glass. A hole is bored radially into each plate, and a thermometer bulb inserted in each hole. The lowest plate rests on a brass vessel, through which cold water is conducted, and on the top plate rests a brass vessel with circulation of warm water. Through holes in the two upper plates (supplied with copper stoppers) the intervals between the plates may be filled with liquid. M. Christiansen experimented first with air, and he proves that its heat-conduction increases with the temperature. The ratio of the conductivity of air to those of several liquids was next studied, the liquid being placed in the lower interval. The results agree well with Weber's figures for absolute conductivity. Some experiments were also made with plate glass (dry and wet) and marble. The method may be adapted (the author points out) to measurement of electric resistances, the potential being measured instead of the temperature.

AMONG some interesting experiments with liquid films, described by M. Plateau to the Belgian Academy, is one in which fine iron wire is first bent to represent a six-petalled flower in outline; the circular centre being supported on a small fork stuck in a piece of wood. The wire is slightly oxidised with nitric acid. The flower is dipped in glyceric solution, and is then put under a bell jar near a window, so that the sky is reflected in the films. A pretty play of bright colours is soon observed, and it continues for hours. Again, with regard to explosion of soap bubbles, one is apt to think the whole of the film is converted simultaneously into minute spherules. M. Plateau has formerly shown that it is not so, and has analysed the course of the phenomenon. An experiment proving the contraction of the bubble during its quick destruction is as follows:—A bubble of glyceric liquid about 11 centimetres in diameter is blown with tobacco smoke, and placed on a ring. Having waited till the top appears blue, you break it there with a metallic wire, whereupon the mass of smoke is shot vertically upwards a dozen centimetres, and then spreads out horizontally, in umbrella shape. It then rises more slowly, and is diffused.

PROF. EXNER of Vienna has lately proved that galvanic elements formed of three elementary substances, one of which is bromine or iodine, give perfectly constant action, and that the electromotive forces exactly correspond to the heat values of the chemical processes. There is no trace of polarisation. Bromine and iodine are also shown to be the worst conductors of electricity at present known. Both bromine and iodine conduct entirely without polarisation, (the latter in solid as well as in liquid condition.) The conductivity rises rapidly with the temperature.

CAREFUL experiments by Herr v. Wroblewski on diffusion of liquids (three chloride of sodium solutions and water) are described in *Wied. Ann.* (No. 8), and yield the result that the constant of diffusion (so far as those experiments go) decreases with decrease of the amount of salt, according to a law of simple proportion. The author further tried a photometric method of measuring diffusion, where the proportion of salt is extremely small; using Hüfner's spectrophotometer and (as colouring-matter in water) nigrosin. He cannot claim great exactness for the results, but the constant is at least one place of decimals smaller than the smallest constant of a salt hitherto known.

DR. KALISCHER, who has been experimenting on selenium cells for the photophone, confirms the observations of Adams and Day that light may in certain cases set up in these cells a photo-electromotive force; the cell becoming its own battery. The same experimenter draws attention to a curious point, namely, that the sensitiveness of selenium cells to light is often greater in cells of high resistance than in those in which, by annealing, the resistance has been greatly reduced. A single cell kept for some months gradually lessened in resistance, while becoming less sensitive to light. These anomalies Dr. Kalischer attributes to the allotropic modifications through which the substance passes, the want of homogeneity accounting also for the photo-electromotive forces observed.

AN excellent paper by M. Gariel has appeared in our contemporary, *L'Électricien*, in which the formulæ for the grouping of cells in a voltaic battery, as deducible from Ohm's law, are discussed and represented in graphic diagrams. M. Gariel has thus arrived at a kind of abacus by which the various problems that arise may be geometrically solved by simple inspection.

PROF. LOVERING of Harvard has lately unearthed from the *Memoirs* of the American Academy a paper by Dr. Nathaniel Bowditch of Salem, Mass., communicated in 1815, in which he investigates the figures made by a double pendulum which compounded two vibrations at right angles to one another. This research, which was illustrated by several plates of figures, therefore antedates that of Lissajous, to whom the discovery of these figures is usually accredited, which was published in 1857. Bowditch investigated the cases of the ratios representing unison, the octave, the twelfth, and the double octave. Bowditch was himself inspired to this investigation by a paper written by Prof. Dean of Burlington, Vermont, in which a compound pendulum, identical with that known as Blackburn's pendulum, was used to illustrate the motions of the earth as viewed from the moon. Blackburn's pendulum dates from 1844. Sang, in 1832, used vibrating wires to compound rectangular vibrations; and Wheatstone's kaleidophone dates from 1827.

SELF-LUMINOUS photographs capable of shining in the dark can be made, as Eder has shown, by laying a transparent "positive" upon a sheet of Balmain's luminous paint, and then exposing the latter to sunlight. The photograph thus produced is a "positive" also. It lasts, of course, only for a limited time.

DR. MÜLLER-ERZBACH, who has just made an exhaustive examination of the desiccating powers of different substances, states that there is no perceptible difference between the power of concentrated oil of vitriol, glacial phosphoric acid, and solid caustic potash in this respect, and that caustic soda and chloride of calcium are only slightly inferior, the difference in tension of aqueous vapour between phosphoric anhydride and anhydrous chloride of calcium being a fraction of a millimetre in the barometric column. He also states that caustic soda is absolutely dehydrated by being shut up in a desiccator with caustic potash.

SOLAR PHYSICS[1]

LIEUT.-COL. DONNELLY, R.E., made the following introductory remarks to Prof. Stokes' first Lecture, which was the first of the series:—

I greatly regret both for your sake and my own that I should have to detain you for a few minutes from the lecture which we have all come to hear. It has, however, been considered desirable that some explanation should be given of what has led to the formation of this Committee on Solar Physics, and what has led to the giving of these Lectures. I am glad to say that in engaging your attention for a few minutes I shall not seriously curtail the time that Prof. Stokes will have at his disposal, for he has been good enough to undertake to lecture on Friday in place of General Strachey, who unfortunately cannot give the lecture which has been announced for him.

[1] Introductory Lecture by Prof. Stokes, Sec.R.S., in the South Kensington Museum Theatre on Wednesday, April 6, 1881.

Our history commences in the year 1875, when the Royal Commission on Scientific Instruction and the Advancement of Science made their eighth and final Report, strongly recommending the establishment, by the State, of an Observatory for Solar Physics. They say that their opinion is confirmed by the action which has been taken by foreign countries in this matter, observatories for astronomical physics having been already established in various parts of Italy, while their immediate erection had been determined on at Berlin and in Paris. The Royal Commission further hoped that similar institutions might be established in various parts of the British Empire, and they particularly called attention to the great advantages that India, at certain high-level stations, affords for continuous observations, which are so important in this matter. In 1876 a very large and influential deputation from the British Association had an interview with the then Lord President of the Council, the Duke of Richmond and Gordon, with the view of urging on the Government the necessity of taking action on this and other recommendations of the Royal Commission. In replying to that deputation the Duke of Richmond pointed out that in a certain small way he had already done something in the matter, for Mr. Lockyer had been transferred from the War Office to the Science and Art Department, and facilities were being afforded him for carrying forward that portion of the researches upon this subject which he had been engaged on for several years.

The representation by the Council of the British Association was followed by a memorial from a number of eminent men of science. I need only mention, among others, the names of Adams, Andrews, Broun, Joule, Clerk Maxwell, Roscoe, and William Thomson, to show you how influential a memorial it was. They based their appeal for the formation of an observatory for astronomical physics on the fact that in the opinion of a considerable number of scientific men there was a more or less intimate connection between the state of the sun's surface and the meteorology of the earth, and they called attention to the fact that recent investigations on the part of several independent men had led them to the conclusion that there was a similarity between the sun-spot period, periods of famine in India, and cyclones in the Indian Ocean. They conclude by saying, "We remind your Lordships that this important and practical scientific question cannot be set definitely at rest without the aid of some such institution as that the establishment of which we now urge." It was under those circumstances that the Lords of the Committee of the Council of Education referred the question to Prof. Stokes, Prof. Balfour Stewart, and General Strachey for their opinion as to whether a start could not be made, and most of what is required by the memorialists in the way of daily accurate observation be accomplished by utilising the advantages offered by the chemical and physical laboratories at South Kensington, with the aid of the detachment of Royal Engineers stationed there. I need not trouble you with the terms of the reference. They are given in Lord Sandon's letter of August 13, 1877, which is printed in a Parliamentary paper as a return to an address of the House of Commons moved by Lord Lindsay on March 20, 1879. I may, however, quote one sentence from it: "Although we are not at present in a position to consider the establishment of an official observatory on a comprehensive scale, we believe that some advantage can be gained if a new class of observations can be made with the means at command; since the best method of conducting a physical laboratory may thus be worked out experimentally, and an outlay eventually avoided which, without such experience, might have been considered necessary." I should also mention that Lord Sandon in his letter suggested that the Astronomer-Royal should be consulted on the subject, and he stated that "We propose to ask General Strachey to act with you especially with a view to advising us as to how far any arrangements made at South Kensington may be worked with, or form part of the system of observations which, we are informed, are in contemplation for India." Just at that particular time the Indian Government had made arrangements for having daily photographs taken of the sun's disk at Dehra-Doon in the North-West Provinces, by Mr. Meins, who, while he was a sapper in the Royal Engineers, had been trained by Mr. Lockyer. The Committee to which I have already referred reported at the end of 1877, and they state what in their opinion may be done at once and without entailing any serious cost. This report is also given in the Parliamentary paper to which I have alluded. Nothing however was done at that time, and in November, 1878, the Duke of Devonshire, as Chairman of the Royal Commission on Scientific Instruction and the Advancement of Science, wrote again calling attention to the subject, and strongly urging that the Report of this Commission should be acted upon. In 1879 a small sum, 500*l.*, was taken in the estimates for the expenses of the Committee on Solar Physics. And this has been continued ever since. As soon as that vote had been put into the estimates with the sanction of the Treasury, a Committee was formed consisting of the gentlemen whom I have already mentioned, namely: Prof. Stokes, Prof. Balfour Stewart, and General Strachey, to whom were added Mr. Norman Lockyer, Capt. Abney, and myself. The object of this Committee is to make trial of methods of observation, to collect observed results, to find out what is being done in foreign countries, and so far as possible to collect and bring together all information on this subject, and finally to reduce the Indian observations which have been made since the time that Mr. Meins was sent to India. The Committee made a preliminary report last year, which was presented to both Houses of Parliament, and has been published. I therefore need not trouble you with any of the information contained in it. You will there see what the Committee has been doing, and what arrangements have been made for carrying on the Indian observations since Mr. Meins' death.

While the Committee has been thus acting in its corporate capacity, certain of its members have been carrying on independent researches of their own on different branches of the subject. The results of those researches have been published in the *Proceedings* of the Royal Society, but from the necessarily fragmentary manner of publication, it has no doubt been very difficult, even for men of science, to follow what was being done. Acting, therefore, on a suggestion made by the President of the Royal Society, the Lords of the Council asked the Members of the Committee to give a course of lectures which should bring in a more or less popular manner the results of their researches before the public. It is to that suggestion that this course of lectures is due. So much for the Committee. But I trust you will excuse me if I touch upon one other subject. It is now just within ten days of eighty years since Dr. William Herschel read a paper before the Royal Society which was headed "Observations tending to Investigate the Nature of the Sun in order to find the Causes or Symptoms of its Varying Emission of Light and Heat," and so on. But for the time I have already occupied, I should like to have read to you some portions of this paper, which are very striking even at the present moment. I will however only say now that he followed this paper by another one on May 14, 1801, on "Additional Observations tending to Investigate the Nature of the Sun in order to find the Causes or Symptoms . . . . and a Few Remarks to remove Objections that might be made against some of the Arguments contained in the former Paper." In those papers Dr., or, as he was afterwards, Sir William, Herschel very strongly and forcibly urges the importance of a continued observation of the sun's surface and of the sun-spots. He investigates the connection of sun-spots as far as the periods were then known, with cyclones, with the prices of wheat, and other terrestrial phenomena, and he points out of what great advantage continuous observations upon this subject were likely to be. My colleagues can tell you better than I can, and no doubt will in their lectures, what has been done in this matter since the days of Sir William Herschel. I am afraid it is not very much—I mean of course in the way of continuous observations—and yet during the interval a step has been made in the instruments of research almost, if not altogether, as great as that made in astronomy by the discovery of the telescope. I refer to the use of the spectroscope. Now, the use of this instrument, the spectroscope, so far as solar and stellar chemistry is concerned, is no doubt due to a magnificent research by Kirchhoff published in 1859. But I think I may be allowed to call your attention to a statement made by Sir William Thomson in his address to the British Association in 1871. He there says that some time prior to the summer of 1852 he had been taught by a certain distinguished professor at Cambridge the fundamental principles upon which this process of investigation proceeded. I need scarcely, I hope, tell you that I am not endeavouring to introduce parochialism into what should be the cosmopolitan regions of science; nor less am I claiming priority for one who I am sure would be the first to repudiate such a claim. But I think you will agree with me that it is rather a striking example of the fitness of things that it is the distinguished physicist to whom Sir William Thomson referred who will give the introductory lecture of this course.

PROF. G. G. STOKES, F.R.S., then delivered the following lecture :—

Some of my colleagues have applied themselves with industry and with remarkable success to various questions connected with the physics of the sun. I am not in that happy condition. I have however been requested to open this course of lectures on Solar Physics. In doing so I will touch but lightly on the labours of my colleagues, because they are going to lecture themselves, and they will be far better able than I should be to expound their own researches. As to the subject of the lecture I have pretty nearly a *carte blanche* before me, and I may choose my own ground. I propose to refer briefly to what is known on the subject and what speculations were made respecting the physical constitution of the sun some considerable time ago, and then to indicate how our notions gradually came to be changed.

Now I need not dwell on the importance of the sun to man. The savage knows how important it is, how man is dependent upon the sun for light and heat; but the man of science knows that, to a far greater extent than the savage can imagine, man is dependent upon that great central body of our system for almost his whole supply of light and heat. For if we want light at night, what do we do but light a candle, or whatever else it may be? If we want more heat than we get directly from the sun we light a fire; but whence comes that fire? In England we commonly use coal; and whence came this coal? An examination of the products of the coal-fields shows that they are the remains of extinct vegetation; and if we may assume that vegetation went on in past geological ages according to the same laws that we observe at the present day, the supply of the carbon, upon which we are mainly dependent for the heat given out in the combustion of the coal, was derived from the air. But in the air it existed in the state of carbonic acid, to which we reduce it in the process of burning; and it was under the influence of light that, by some process the details of which we cannot explain, the carbonic acid was decomposed and the carbon appropriated. So again as regards our supply of light: if we light a candle we make use of what is derived from the fat of animals; they are unable to decompose carbonic acid, and are dependent on vegetables for their food; so that directly or indirectly we come to the agency of the sun. We see therefore how important the sun is to man. But independently of its great importance, it presents us with features of extreme interest, which are calculated to excite the liveliest curiosity in the man of science.

The question arises, first, Is the sun always in precisely the same condition? For more than two centuries it has been known that there is a change in its appearance which has been observed from time to time. I allude to the dark spots which appear on its surface. Those spots are seen to move over the disk of the sun, not with a uniform angular motion, as if there were some body interposed between us and the sun, and circulating around it, but nearly as if they belonged to a solid globe rotating on its axis. I say nearly, but not quite in the same way, because it is now well established by the labours of the late Mr. Carrington, that if we attempt to determine the time of rotation of that body on the supposition that the spots were stuck to it, we obtain different results according to the place of the spot on the sun's disk. As I have said, taken as a whole the spots move nearly as they would do if they belonged to a solid globe to which they were stuck, and in that way we may determine approximately at least the direction of the sun's axis of revolution, or equator. Now Mr. Carrington found that the spots which are situated a short distance north and south of the equator, taken by themselves alone, would indicate a more rapid period of rotation of this body than those which are situated nearer the poles. (They are never found for some considerable distance round either pole.) Associated with those spots there is another appearance called faculæ, which are ridges of extra brightness on the surface of the sun, and which have an evident relation to the spots. They are ordinarily in the neighbourhood of the spots, and moreover—and this is a point worthy of consideration with reference to any theory as to the formation of the spots—it is found that sometimes faculæ will break out at the surface of the sun where there is no spot, but there is certain to be an outbreak of a spot or spots not long later. Besides this outward appearance, which can be seen with even moderately good telescopes, fine telescopes show that the whole of the surface of the sun has a mottled appearance, consisting of portions, some more, some less, bright. It is dotted over with small specks, having the general character of minute specks of bright light. [Photographs of the sun's surface, including a large-scale one, by Janssen, of a small portion, were here exhibited.]

These dark spots are constantly in a state of change, which goes on from day to day, and the finer mottlings change with very great rapidity indeed, so that M. Janssen found that two consecutive photographs taken quickly one after the other did not show the mottling identical; two photographs taken at the same instant did.

Now what notion can we form as to the nature of these spots? One important matter to know with respect to any speculation about their nature is, whether they are elevations or depressions. Mr. Wilson showed even in the last century, by observations of them as they changed their position on the sun's disk by the sun's rotation, that they were below, and not above, the general surface; and to the telescope they give the idea of a hole in a luminous envelope, through which you look down upon something dark beneath; and so the older astronomers adopted the notion that the sun was surrounded with a luminous envelope which they called a photosphere, and that the body of the sun itself was, not absolutely, it may be, but at any rate comparatively speaking, dark. Indeed, Sir William Herschel went so far as to speculate on the possibility of the sun being a habitable globe. How this great luminosity could possibly be kept up around a vast globe like the sun, generally dark and accordingly at a comparatively low temperature, they did not explain, and in fact you must suppose, on this hypothesis, that the true state of things at the surface of the sun is quite unlike what we have at the surface of the earth. Now we must endeavour to make our theories as to the nature of the phenomena which present themselves rest upon known laws as far as we can. Sir John Herschel, indeed, conjectured that possibly the body of the sun might be defended from the heat of the envelope which, as we know on earth, radiates so fiercely into space, by a perfectly reflective canopy. But where are we to get a perfectly reflective canopy? The only example we know of perfect reflection is that of total internal reflection, where rays of light or heat, as it may be, fall with sufficient obliquity on the surface of separation between a denser and a rarer medium, the rays being in the denser medium.

The nearest approach we know to total reflection, leaving that case out of consideration, is that of polished silver; but polished silver, although it reflects by far the largest quantity of the light falling incident upon it, by no means reflects the whole. If a globe like the sun with an envelope of polished silver were surrounded by an intensely glowing body, the globe would not remain cold, at least if we are to rest upon the experiments which we can make in the laboratory. Yet this idea of a dark solid body remained in the mind of astronomers for a long time. I will read a passage from Sir John Herschel's "Outlines of Astronomy" about what the spots are :—"Many fanciful notions have been broached on this subject, but only one seems to have any degree of physical probability, viz. that they are the dark, or at least comparatively dark, solid body of the sun itself, laid bare to our view by those immense fluctuations in the luminous regions of its atmosphere, to which it appears to be subject." This sentence remained unaltered even in the edition of Sir John Herschel's work published as late as 1858.

It was, I think, in 1854, that Sir William Thomson—whom I am happy to see before me—threw out another speculation as to the nature of the heat of the sun. First I should say, perhaps, what it was not supposed to be. If we abandon the idea of a body remaining cool within an intensely glowing envelope surrounding it on all sides, and suppose that the sun is really exceedingly hot, where are we to suppose the source of that heat to be; in fact, what origin are we to attribute to the source of the heat which we know as a fact to radiate from the sun, wherever it may come from? The most natural supposition would be that of primitive heat. Take the sun, that is to say, existing as it was ages ago; starting from that point, then, you may imagine it to be sending out heat all these ages and gradually cooling itself down. Now there would be one very strong objection to that theory if you supposed that the sun was a solid body. It might be glowing, but unless the conducting power were enormously greater than anything we have reason to suspect from experiments we can make on earth, the surface would very quickly cool down and become comparatively dark. The notion of a solid body must be given up if we suppose that primitive heat is the source. It must be at least liquid, and that liquid must be in a state of constant agitation.

Objections, however, occurred to Sir William Thomson's

Digitized by Google

mind to such a view, and they led him to adopt another, that the heat was due to the impact of meteoric bodies falling into the sun. The surroundings of the sun may be considered to consist of a vast number of meteoric bodies similar to the shooting stars which we see when they come across the earth's atmosphere. An assemblage of such bodies reflecting in a measure the light of the sun may possibly constitute the zodiacal light. Now if these bodies are continually falling into the sun their impact will produce an enormous quantity of heat. I should mention that this idea had been thrown out previously by Waterston, but Sir William Thomson made an important change in it by supposing that instead of being dependent on meteoric bodies casually falling into the sun from the stellar spaces, there is a supply of such bodies circulating round the sun and gradually falling into it. He showed that the heat produced by such impacts would enormously surpass the heat of combustion of the most combustible substances we know on earth. This theory attributes the heat of the sun to something outside itself; what I may call, in contradistinction to that, primitive heat, attributes it to what is inside the sun, to the body itself. According to the meteoric theory the seat of the most intense action is at the surface of the sun itself. The old theory of a comparatively cool nucleus is here given up, and the sun is allowed to be a glowing body, molten, doubtless; but still the most intense action is supposed to take place on the surface of the sun. With regard to the spots I think the idea of Sir William Thomson at that time was that there were great whirlwinds at the surface of the sun from time to time which blew away these meteors, and consequently caused, where they existed, a less intense succession of impacts, and consequently less heat, and that a portion became comparatively dark. I just mention this hypothetically. I will not at present say anything about the very important information which the spectroscope gives us respecting the sun, but will reserve that to a later period.

A different theory was thrown out by M. Faye in 1865. According to this the interior of the sun is intensely hot, and for that very reason, as M. Faye supposed, comparatively speaking non-luminous. He conceived, in fact, that the interior was so hot that bodies were there in a state of dissociation; and as we know that many a glowing gas gives out plenty of heat, but comparatively little light, so it was supposed that the interior of the sun, by virtue of its intense heat, radiated only comparatively little light, and that it was not until the substances of which the sun was composed came to the outside that they became cool enough to enter into chemical combinations, and to supply us with substances which were capable of emitting an abundance of light. Now here there is one feature in common with the old views, namely, that the source of the light is supposed to be a photosphere surrounding a solid body which is, comparatively speaking, dark; but the reason why this body is supposed to be dark is precisely the reverse of that which was supposed in the older views. In the older views the body of the sun was supposed to be comparatively cool: here it is supposed to be so intensely hot that the substances of which it is composed have not yet got into a state in which they can emit much light. According to this theory the spots are places where the photosphere is, so to speak, blown away, and you see down into the intensely hot body of the sun, which is comparatively feebly emissive of light. This view seemed to receive some support from a remarkable discovery made by Mr. Huggins in 1858 with reference to the constitution of the planetary nebulæ. On applying the spectroscope to these planetary nebulæ he made a remarkable discovery, that the spectrum which they emit consists exclusively of bright lines, such as the spectrum we know to be produced by an incandescent gas. Many of these nebulæ have a somewhat stellar nucleus, which seems to exhibit a spectrum of a more ordinary character. Now at first sight this condition of things appeared to be just what the theory of M. Faye required, and to give an explanation of the phenomena according to that view. These planetary nebulæ give out a feeble light compared with the stars; and so, when seen through an aperture in the photosphere, we may suppose that the interior gaseous portions of the sun are too hot to glow with more than this feeble light.

Now that supposition is in contradiction to a very important extension of Prevost's theory of exchanges which was made independently by Prof. Balfour Stewart—who is here present, I am happy to see—and by Prof. Kirchhoff. According to Prevost, if you have a body contained within a heated envelope, and everything has come to its final state, and this envelope is opaque, then all the bodies within it will be at the same temperature. They will receive as much heat from the envelope as they give out by radiation, and when all is in perfect balance between the radiation and the absorption one of those bodies is comparatively transparent, letting a good part of the heat which it receives from the envelope will give out itself comparatively little heat, otherwise it gradually become cooler. Now the extension I have spoken of is that this is true not merely of the sum total of the heat given out or absorbed, but of each particular kind of heat or light which that total consists; so that if we take light of a certain degree of refrangibility, there is a balance between what is absorbed and what is given out.

Now this extension of Prevost's theory throws upon Faye's theory of the constitution of the sun an important situation of the spots. For, take the interior of the sun, we take light of any particular degree of refrangibility, that is, this supposed gas which constitutes the body, that is, will be either opaque as regards that kind of light or transparent, or partially transparent. If it is certain to emit light of the same refrangibility. If it is parent, then the spot would not be dark, because, as through; just as in the planetary nebulæ we do not see the kind of light for which this interior gas was which we ought to see the opposite side of the photosphere has every reason to suppose to be a nucleus of the nebula right through its enormous semi-diameter. The appreciable angle, but the planetary nebulæ subtend an appreciable angle, which can be measured, and is of judging by the distance of the planetary nebulæ from us dimensions are gigantic as compared with the average stars, and as compared in all probability with our Therefore there ought to be seen in the sun, on that the same phenomenon as is seen in these planetary namely, the photosphere on the far side shining gaseous globe. It seems to me that that considerable acceptance of M. Faye's theory as a whole, and have recourse to some other.

Now I have mentioned already Sir William meteoric theory, in which is involved the very imposed deration of the conversion of work into heat. I do all, in stating some possible objections to that theory has himself since given up), to go against the supposition original source of the sun's heat may have been the work into heat, but starting with the sun as it was ago, has the subsequent heat been derived from the outside? According to the theory of M. Faye, to would be derived from the sun itself, which would its heat gradually. So far (giving my own view probable) it seems to me that the probabilities are that part of the theory. Well then, if the spots are dark body of the sun being exposed by something being from the outside, be it that the body is dark from of heat or from an excess of heat, what may we suppose be? In a paper published in the *Philosophical Transactions* Messrs. De La Rue, Stewart, and Loewy, the advocated the view that the spots are due, not to an from the centre of the sun, but to a down-pour of of the matter which has been ejected from the sun. think I cannot go on without going back to some remarks which the spectroscope plays a most important part. Prof. Kirchhoff that we owe the first extensive application spectroscope to the study of the sun. He held that in the state of incandescent gas give out bright lines spectrum, according to the extension which he made, dently of Prof. Balfour Stewart, of Prevost's theory changes, these glowing gases ought to absorb light of refrangibility coming from a body behind. Now if glowing gas in front of an opaque body glowing at temperature, you ought to see neither dark nor bright the gas would absorb the light of the refrangibilities gives out, and it would not absorb the light of the which it does not give out, so that in the region of lines we should, even if the body behind were away, get amount of light due to the temperature, coming from the gas itself; in other regions where there is no such bright coming from the gas, you get the full amount of light from the opaque body behind. But if you suppose the front, glowing though it be, to be at a lower temperature the opaque body behind, then it would absorb more light

Digitized by Google

ming from the body behind than it irtue of its own emission, and accord- place of those bright lines, or what gas were there alone, dark on a bright that theory he was enabled to identify lines in the solar spectrum with the ements which we know at the surface magnesium, and so forth. Now this ht on the constitution of the sun. It outer, and, comparatively, therefore there must still be a temperature so the boiling-point of iron, and above of the most refractory metals. And pplication of the spectroscope which hom I see before me. First I should say bserving a total solar eclipse, a new , or at least a phenomenon which, if ly attracted general attention. The was seen to be surrounded by rose- ring the appearance of mountains, uld possibly be their nature? We had them; the greatest duration of a total over four minutes, and these eclipses two years or so, and when they occur trip along the earth's surface of only a probably a great portion of it falling were there present in a ship we could ons but what could be taken by the these prominences and the nature of fore a slow matter to get on with, so to the observation of them during se. The change of height of those ey belong not to the moon, but to the oon moved over the body of the sun ed to the sun, tend to get shorter and ed in, and would reveal themselves behind the opposite side, which is Soo special provision was made for rominences, and Mr De La Rue in- photographs, which led to some most showed, among other things, that in , whatever they were, were not at all sun, but were suspended as clouds ut, therefore, be mountains clearly. iderable time prior to 1868, had been hle mode of rendering those promi- their nature without waiting for or rare phenomenon of a total eclipse. minences gave out consisted of bright spectroscope of high power to the night so far reduce the intensity of f the spectrum where there is the the immediate neighbourhood of nder them visible. At last he s, and the announcement of this the Royal Society. Meanwhile nt to India to observe a total ject which he took up was to observe dinences, which he did with success. y should not this be done any day?" he succeeded. In point of absolute servation of Lockyer, although at the eached this country, so that the two independent of each other. Well, the method of observing those pro- see them at will, so that they may be when we choose, from hour to hour, e forms of them can be seen, and it is astounding velocity. They are pro- n with a velocity sometimes of 100 or nd. Their forms were such as we the ejection of gas from the body of jectured that they might be of the s. Their features however indicate of actual matter from the sun, and ir motion indicates the same. This f the vastness of the changes which the surface of the sun. of these changes? It seems to me that we can form respecting them is something derived from what takes place in our own earth, and what we can observe here. Suppose the sun to be shining, we will say on a summer's day. If we look horizontally with a telescope everything is seen to be in a state of tremor; the air is far from homogeneous. What is the reason of that? The greater part of the sun's heat passes through the upper strata of the atmosphere and reaches us, the air being transparent with regard to a large portion of the sun's heat. It warms the surface of the earth. That in turn warms the air in contact with it, and further radiates forth heat of a kind for which the air is opaque. The consequence is that the lower portions of the air in contact with the earth get warmer, and that unequally according to the nature of the ground—more on stones and gravel, for instance, and less on grass and so forth. Being warmer they get lighter, and therefore there is a constant ascent, a constant mixing of the hot and cold portions by currents of convection. As this goes on continually a stratum of air of considerable height becomes warmed in this manner, and sometimes an exchange by convection or something of the nature of convection takes place on a very grand scale. Let us take the case of summer weather. Suppose we have a succession of hot days accompanied by a good deal of evaporation, gradually these several currents of convection cause a warming of a stratum or air below of considerable height, which is also well supplied with moisture from the evaporation. At last, taking the stratum as a whole, the equilibrium becomes unstable, and there is an uprush; hence there is a kind of chimney formed, through which the air flows upwards, and then spreads out laterally overhead. This appears to be what takes place in our summer thunderstorms. The heated and moist air forms for itself a chimney, and in ascending there is a rapid deposition of what was previously vapour of water in the now condensed state of water itself, and a rapid fall of rain occurs after a time. This appears from some cause or other to be the occasion of the development of a great deal of electricity, which is manifested in the form of lightning. While this action goes on you have the in-draught towards what I will call the chimney from all sides; the vapour sooner or later gets condensed, and there is a fall of rain accompanied by lightning. Sometimes there is hail even in summer; for when the air charged with vapour gets to a particular height the vapour becomes condensed and forms rain; but it may be that the stratum of the upper air that is pierced through is below the freezing-point, and, the rain falling through this, it gets frozen. I will just call attention to one fact; according to this view, you see you may have a general current of wind over the country—say, for the sake of illustration, from west to east. Suppose there is a region to the west where an ascending current has been formed; then there is an in-draught from all sides to that place, and when the thunderstorm has not yet come on you are in a comparative calm, because the general direction of the wind being from the west, and the in-draught carrying the air from the east, the two together tend to neutralise one another; or you may have actually a wind blowing towards the region of the thunderstorm. Accordingly we know people often say that thunderclouds move against the wind. I shall have occasion to refer in my next lecture to the development of atmospheric electricity in reference to some speculations in regard to phenomena accompanying changes in the condition of the sun; but at present I merely refer to this process as illustrative of what seems to be the most natural supposition to make regarding the origin of these disturbances which are found to be continually taking place at the surface of the sun. The outer portions of the sun are the source of a gigantic amount of radiation of heat and light which passes out in all directions. By this radiation those outer portions must tend to a certain extent to cool down, and consequently, as the same physical conditions hold good, if the same physical laws hold good, at the surface of the sun that we have on our own earth, you may easily suppose that, having become cooler than they were, the substances become specifically heavier, and accordingly give rise to currents of convection similar to those that we have in our own atmosphere from a similar cause, but operating in one respect in a different way, because in the solar atmosphere there is a cooling from above, but in that of the earth a heating from below. Those minor currents of convection ascending and descending naturally enough give rise to that mottled appearance which is always seen on the sun's surface, because if the interior of the sun be hotter than the portions which have cooled by radiation, then the ascending portions would naturally, being at a higher temperature, be brighter, the descending portions darker, and small

Digitized by Google

(comparatively speaking) descending currents may very likely, as it appears to me, be the cause of these appearances. Now just as at the surface of the earth these minor currents of convection are continually going on, and mixing up the heated portions below with less heated portions above, till at last a great catastrophe takes place, and we have a thunderstorm or even a cyclone; so the same thing may take place at the surface of the sun, and minor currents of convection may gradually cause a cooling of a greater stratum, and at last the equilibrium becomes unstable, and a great change takes place between the superficial portions and those which lie beneath, and we have the manifestations of faculæ and spots. According to this view the faculæ would consist of the heated portions on a larger scale coming from the interior, and the spots of a subsequent down-rush on a large scale of the portions which had been erupted and had cooled by radiation. Kirchhoff supposed that the spots were due, not to depressions of the sun, but to clouds of comparatively cool gases or vapours rising above the general surface. This was in contradiction to the relative altitudes of the sun-spots and the general surface as made out originally by Wilson, and subsequently confirmed by the observations of others; and moreover there are some other difficulties connected with it. Let us suppose that there is an eruption of hydrogen which has got cool, then if that exists and there is a cold draught at some distance above the sun, we cannot say it would absorb any longer the rays which it is capable of absorbing when glowing, because the correspondence of emission and absorption only necessarily holds good on condition that the substance is at a given temperature. If the temperature changes it is possible, and in many cases we know it is a fact, that the mode of absorption may change with it. We know that the cold hydrogen is transparent; we know, theoretically at any rate, that glowing hydrogen must be opaque with regard to light of the particular refrangibility which it emits; hence a cool mass of gas might cease to be opaque even by virtue of its being cooled. Again, if we had a cloud of, say, vapour of iron, and if this were condensed into actual drops or globules of molten iron in the upper portion of the atmosphere, they would form such a very rare sort of mist as would be something like a very rare haze which barely obscures the sun, and would not give rise to more than a slight general darkening. But if the gases in descending got warmed again, they would then be in a condition to absorb light specifically; but being at a lower temperature than the sun they would not give out nearly so much light as they absorb.

That seems to me to be the most natural explanation of the spots and of the phenomena attending them. I may have something more to say about this on a future occasion; but, as I see the time is going on, it would probably be more agreeable to you that I should postpone anything further I have to say to you upon this subject until my next lecture, in the course of which I hope, as I have said, to point out a speculation as to the connection which exists between sun-spots and certain phenomena which we know exist at the surface of the earth. There are probabilities to my mind in favour of it, but I will, with your permission, defer allusion to it to my next lecture.

(*To be continued.*)

THE HELVETIC SOCIETY OF NATURAL SCIENCES

THIS Society held its sixty-fourth annual session at Aarau on August 8, 9, and 10, under presidency of Prof. Mühlberg, whose opening discourse treated of recent progress in physiology and chemistry. An account of the proceedings (of which we here offer a brief *résumé*) will be found in the *Archives des Sciences*.

In the Section of Physics and Chemistry Prof. Forel read a valuable paper on the periodic variations of glaciers. These periods of advance and retreat are proved to embrace several years (five to twenty and more); they are due in the first instance mainly to variation in velocity of the glacier, and this to small variations in the thickness of the *névé* repeated in the same sense for several years, the consequent variation of velocity becoming much more pronounced as the glacier descends, and the ultimate effect being separated by many years from its original cause. The varying heat of summer appears to be of quite secondary importance. In one of three papers, communicated by M. Raoul Pictet, he described his new method of distillation and rectification of spirits by a rational use of low temperatures. The two processes are perform economy a purer product is ob the principle of his rapid st working of which will be w treated of the different qualitie and permanence of magnetic ceding, reference has been alre

rhythmical contractions in the wing membranes of bats (Luchsinger).

In the Botanical Section M. Buser read a paper on Swiss willows, and Prof. Schnetzler gave some observations on the vegetation of *Lathræa squamaria* on tree-roots.

To the Section of Geology M. Jaccard submitted a project of maps of the "erratic phenomenon" in Switzerland, on the plan of those constructed by MM. Falsan and Chantre for the Rhone Valley. Dr. Rothpletz discussed the *rôle* of faults in the geology of the Alps, showing that these are by no means exceptional, and deserve more study than they have hitherto had. Dr. de la Harpe presented a collection of Egyptian nummulites. Dr. Gillieron had a paper on the age of the red schists of the Simmenthal. Prof. Mayer-Ermann furnished proof that the Loire must have flowed into the Parisian Gulf of the North Sea during the whole Eocene period, and that it was only at the end of the Inferior Neogene or Aquitanian epoch that it made the bend at Orleans and entered the Atlantic. The Pleistocene of Central Europe formed the subject of an instructive paper read by Dr. Rothpletz at the first general meeting.

In Medicine a paper was read by Dr. Bircher on the extension of deaf-mutism in Switzerland, and its relations with goître and cretinism. He finds that these three are merely different manifestations of one and the same principle of degeneracy of race, a principle which, in Switzerland, is endemic in the Triassic, Marine Molassic, and Eocene formations.

THE ARCHÆOLOGICAL CONGRESS AT TIFLIS

THE proceedings of this Congress, recently held at Tiflis, were both interesting and animated. No less than 700 members arrived at Tiflis from various parts of the Caucasus, and fifty-five from various parts of Russia. The foreign members were few—Prof. Virchow, who took advantage of his stay in the Caucasus to make an excursion to Ossetia, and Messrs. Aeger and Hubsch from Vienna. The Congress was opened by Count Ouvaroff in one of the halls of the palace, before an audience of about 800 persons. The President of the Congress, M. Komaroff, pointed out that the Congress had met with much sympathy from all interested in the study of the Caucasus, as well as much help from the teachers of primary and secondary schools, who had sent in many interesting objects for the exhibition. We notice among the objects exhibited a most interesting collection of bronze antiquities from Ossetia, Bosphorian antiquities from a *kourgan* of the province of Kouban, stone implements from Tzalka, Georgian ornaments and stone implements from the provinces of Novgorod and Tver. Ossetia has been known for many years for a great find of interesting bronze implements, of figures of animals, curved hatchets with spirals and zig-zag ornaments and with figures of animals, as well as religious objects belonging to some unknown worship; the collection, which was bought some time ago by M. Chantre, is very complete, and will soon be described by him. The new collections from a *kourgan* at the Sievers Station consist of massive gold, and represent subjects of Greek mythology. On the same day the excellent Caucasian museum which was founded several years ago, but was closed for two years for unknown reasons, was re-opened.

Count Ouvaroff made an interesting communication on the remains of the Stone period which were found near Irkutsk, on the bank of the Angara River, at Talminskoy village. Many human skeletons, with stone and bone implements, and perforated teeth of animals, were found there, together with hatchets of jade (nephrite), which numbered as many as two hundred. This is the first find of jade implements in graves in Russia. This communication gave rise to an interesting discussion, during which M. Moushketoff, the well-known traveller in Turkestan, spoke of the great monolith of nephrite at Samarcand, on the grave of Tamerlane. It has the shape of a parallelopiped, 7·8 feet long, 1·5 foot wide, and 1·2 foot high, and weighs about 1800 pounds, whilst the greatest pieces of nephrite which are found in boulders do not weigh more than 700 or 750 pounds. It is well polished, but is broken through its centre. The rock resembles very much that of Khotan. As to the places where nephrite is found *in situ*, our knowledge is still very limited. Messrs. Shaw and Hermann Schlagintwert have seen nephrite mines in the Kwen-Lun, close by Balaktchi, at a height of 12,000 feet; according to Dr. Stoliczka it appears there as veins in chlorite-slates and quartzites. Two other places where nephrite is found are known north of the Kwen-Lun Mountains, close by the Kilian Pass, at a height of 6070 feet, and near Kamat village on the highway to Khotan, at a height of 5790 feet; a fourth is presumed to be at the sources of the Yourson-tush, or Khotan River. But the nephrite implements which we found in graves were mostly made from boulders of this rock, which are often found in Eastern Siberia on the shores of Lake Baikal, and on the Boutogol Mountain in the Sayan Highlands; however, we do not know that nephrite was found *in situ* in these latitudes. All implements which are in the St. Petersburg museums were made of nephrite from Eastern Siberia, whilst the Kwen-Lun jade is used only in recent Chinese products.

Prof. Samokvasoff made a communication on his finds in the graves on the Caucasus, in the neighbourhood of Pyatigorsk. He excavated about 200 graves belonging to the Stone, Bronze, and Iron periods. In the larger graves he found bronze implements together with stone ones, and as there are in these graves, together with bones of sheep, several split human bones which do not belong to skeletons, he supposes that during the Bronze period the inhabitants of this part of the Caucasus were Anthropophagists. This opinion, however, was not concurred in by the majority of members of the Congress.

The chief work of the Congress was in the branches of History and Antiquities; but we notice also a special sitting for communications in French and German, during which several papers were read connected with the natural sciences. Thus Dr. Obst, Director of the Leipzig Ethnographical Museum, read a paper upon the results of the statistical researches on the colour of hair and eyes in Saxony, and M. Smirnoff gave the results of the same inquiries with the Armenians and Georgians of Transcaucasia, as well as with the Russian population of the provinces of Kouban and Stavropol. Out of 2500 Armenian children there were 63 per cent. of dark, 4 per cent. of fair, and 33 per cent. of mixed (fair hair with dark eyes, or *vice versâ*). Of 1400 Russian children there were only 14·5 per cent. of dark, and it is deserving of notice that M. Smirnoff could not discover any difference between Great Russians and Little Russians, the number of fair children being 33·3 per cent. in the former, and 32·0 in the latter, whilst the mixed make respectively 52·2 and 53·5 per cent. As to Georgians and Imers, the observations are not sufficiently wide, but it may be stated that purely dark children are less numerous (50 to 55 per cent.) than with Armenians.

Prof. Virchow gave a long and interesting lecture on the chief problems of the Ethnology and Archæology of the Caucasus, accompanied with some remarks on the civilisation of its former inhabitants. Speaking on the usually-received opinion that the Caucasus was the highway for populations coming from Asia to Europe, Prof. Virchow expressed some doubts as to the crossing of the Caucasian passes by whole tribes at a time when the communications were so difficult and the ice-covering descended lower than now. It would be most important, therefore, to know if the first inhabitants of the Caucasus came from the north or from the south. Speaking further of the Ossetians, Prof. Virchow was astonished not to find among the adult population a single true fair type, which might seem contradictory of former opinions; only among children did he find fair-haired individuals with rosy Flemish cheeks. On the other hand, some measurements have brought him to the conclusion that the Ossetian skull is short and high, very different from the German type of skulls. Dolichocephalic skulls are very rare, and show that the tribes of the Caucasus have undergone much mixture with other people. As to the antiquities found in Ossetia, Prof. Virchow considers that the civilisation they speak of was far more recent than that discovered by Dr. Schliemann at Troy, as it does not contain stone implements, but has, on the contrary, curved fibulæ which were unknown at Hissarlik. The ornaments of the Ossetian bronze-implements, and especially the figures of stags, horses, and mountain-sheep, seem to show a connection between the former inhabitants of the Caucasus with those of the Altai Mountains.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—The following are the courses of instruction in natural science to be given this term at Oxford:—Prof. Odling lectures on the atomic theory, Mr. Watts on organic, Mr. Fisher on inorganic chemistry, and Mr. F. D. Brown on physical

Digitized by Google

chemistry. The Linacre Professorship of Physiology, vacant by the death of Prof. Rolleston, will not be filled up in time for the new professor to undertake this term's lectures. Mr. Hatchett Jackson will give the professorial lectures, taking the nervous system for his subject; Mr. Thomas will lecture on comparative anatomy; and Mr. Robertson will form a class for practical microscopy. Prof. Pritchard will give a course of lectures on the theory of the transit instrument and on the planetary theory, and will form an elementary class three evenings a week at the University Observatory. Prof. Lawson lectures on vegetable histology at the Botanic Garden; Prof. Maskelyne on crystallography; and Prof. Prestwich on the principles of geology at the Museum. Prof. Westwood gives informal instruction on the Arthropoda every afternoon.

At Christ Church Mr. Vernon Harcourt gives a course of lectures on the metallic elements, and Mr. Barclay Thompson a course on the Lemuridæ and Simiadæ. At Magdalen Mr. Yule continues his demonstrations on the chemistry of the tissues and secretions. At Balliol Mr. Dixon forms a class for the determination of the composition and vapour-density of organic substances. At Exeter Mr. Morgan lectures on histology.

At Trinity College the Millard Scholarship in Natural Science has been awarded to Mr. A. E. Field from the Modern School, Bedford.

Treckner.—On the application of the electro-dynamic potential to the determination of ponderomotive and electromotive forces, by R. Clausius.—Description of the spiders hitherto observed at Bonn, by F. Bertkau.

1881.—First half.—The quartzite and slate on the eastern border of the Rhine slate hills and their neighbourhood, by C. Chelius.—On the distribution of animals in the Rhönegebirge and the Main valley with reference to Eifel and the Rheinthal, by F. Leydig.—Contributions to the insect-fauna of the coal-formation of Saarbrücken, by F. Goldenberg.

Memorie della Società degli Spettroscopisti Italiani, July.—Protuberances observed at Rome during the first quarter of 1881, by P. Tacchini.—Two solar regions in constant activity during 1881, by the same.—On the distribution of spots, faculæ, and protuberances on the sun's surface during 1880, by the same.—On direct and spectroscopic solar observations made at Rome in the first quarter of 1881, by the same.

SOCIETIES AND ACADEMIES

VIENNA

Imperial Academy of Sciences, October 6.—V. Burg in the chair.—The following papers were read:—T. Singer, on secondary degeneration in the spinal marrow of dog.—A. Pribram and Al. Handl, on the specific viscosity of liquids and its relation to the chemical constitution.—James Moser (Cambridge), on the microphonic action of selenium-cells.—V. Dvorak, on some acoustic phenomena of motion, especially on the acoustic radiometer.—Boh. Brauner, contributions to the chemistry of cerium metals.—E. Goldstein, on the band-spectrum of air.—T. Schlesinger, a sealed packet relating to the unity of natural philosophy.

LIGHTNING CONDUCTORS.

Experience, accumulated since the time of Benjamin Franklin, proves conclusively that a Conductor made of Copper of adequate size is the best of all appliances for the protection of every description of building from the destructive effects of lightning.

NEWALL & Co.'S PATENT COPPER LIGHTNING CONDUCTOR,

As applied to all kinds of Buildings and Shipping in all parts of the world with unvarying success; is the most Trustworthy, most Effective, and also the Cheapest Conductor ever offered to the Public.

It is simple in its application, no Insulators being required, and it costs only ONE SHILLING per Foot for the standard size, which ensures safety in any storm.

A DICTIONARY OF MUSIC AND MUSICI A

BY EMINENT WRITERS, ENGLISH AND FOREIGN,

EDITED BY GEORGE GROVE, D.C.L.

Vols. I. and II.—Price 21s. each.

Vol. I. A to IMPROMPTU. Vol. II. IMPROPERIA to PLAIN SONG.

Demy 8vo, cloth, with Illustrations in Music Type and Woodcut. Also published in Quarterly Parts, I to XIV. now ready, price 3s. 6d. each. Cloth Cases for binding Vols. I. and II., price 1s. each.

TO BE COMPLETED IN THREE VOLUMES.

"Dr. Grove's Dictionary will be a boon to every intelligent lover of music."—*Saturday Review.*

"What is modestly called a 'Dictionary' might have fairly been entitled an 'Encyclopædia,' for the has included in his scheme everything that belongs to music, or is allied, or is even distantly related to would be a great mistake to regard this work as useful only for the purposes of reference. It is a collec interesting and valuable articles on all kinds of musical subjects, which amateurs, who take a genuine in in the art they profess to love, will read from beginning to end."—*Daily News.*

"We now take leave of this 'Dictionary,' recommending it heartily to our readers as full of mate and amusement."—*The Times.*

"What will strike the reader first of all, perhaps, is the fulness and completeness of the information collected."—*Examiner.*

"As a complete account of the biographical as well as technical materials relating to the art of and its history, Mr. Grove's Dictionary is without precedent in England."—*Quarterly Review.*

"The work, when complete, will supply a want which has long been felt by amateurs and professors art in this country."—*Illustrated London News.*

"This work promises to be for music what the best encyclopædias are to general literature science."—*Guardian.*

"The excellence of the dictionary becomes more and more conspicuous as the work goes on."—*Daily Tr* (New York).

The Society's Lectures at St. George's Hall, Langham Place, on Sundays, commence each Afternoon at Four o'clock precisely. The first Lecture will be—October 3rd, "Monsieur D. Conway, M.A., on "The Heart of Shelley."

Members' Annual Subscription £1. For Tickets and Lists of the published Lectures, apply (by letter including remittance) to the Hon. Treasurer, Wm. Henry Dowsett, Esq., 13, Gloucester Crescent, Hyde Park, W. Payment at the Door—One Shilling (Reserved Seats), Sixpence, and One Penny.

ANDERSON'S COLLEGE, GLASGOW.

THE "YOUNG" CHAIR OF TECHNICAL CHEMISTRY.

Professor E. J. MILLS, D.Sc. (Lond.), F.R.S.

SESSION 1881-82.

The Laboratories will be Open Daily, on and after Tuesday, 1st November, from 10 A.M. to 4 P.M. (Saturdays, to 1 P.M.), under the superintendence of the Professor and his Assistants. Instruction given in the Preparation of Chemical Substances and Original Research, especially as relating to Manufacturing Processes.

Fees—Whole Session of Nine Months, £10; Six Months, £14 10s.; Three Months, £7 10s.; or for One Month, £3 15s.

The New Laboratory Buildings have now been erected and occupied. Students entering upon Laboratory Instruction are required to have a fair knowledge of Elementary Chemistry.

LECTURES.—A COURSE of FIFTY LECTURES on TECHNICAL CHEMISTRY will be delivered during the Session on Monday, Tuesday, and Wednesday in each week, Commencing on November 7. The Lectures will be illustrated by the actual Inspection of Manufacturing Processes. They will include this year, as special subjects, and with a view to the Examinations of the City and Guilds of London Institute, Dyeing and Printing.

Fee for the Course, Two Guineas; Laboratory Students, One Guinea.

The attention of Young Men qualifying for the professions of Civil and Mining Engineers, Architects, &c., as well as those more immediately interested in the study of Manufacturing Chemistry, is called to this Course of Lectures.

A COURSE of LECTURES on TECHNICAL ORGANIC CHEMISTRY will also be arranged for during the Session.

Several PRIVATE LABORATORIES can be placed at the Disposal of INVENTORS, PATENTEES, and Others interested in Technical Research.

IRON and STEEL MANUFACTURE.—Mr. J. SNODGRASS, F.C.S., will Deliver a COURSE of EVENING LECTURES on the Subject in connection with the City and Guilds of London Institute, in time for the May Examination.

Glasgow, 128 Hope Street, 30th September, 1881. ALEX. MOORE, Secretary.

INSTRUCTION IN MATHEMATICS.

STUDENTS wishing for Assistance in Mathematics can be attended at their own homes by a Cambridge Graduate, M.A., F.R.S., on very moderate terms. Address O. P., 18, Swakeley Terrace, Shepherd's Bush, W.

WANTED.—OFFERS for the Last 6 Vols. of NATURE complete, with Engravings, ready for Binding.—Address J. Hannen, Wick, near Arundel.

EQUATORIAL NEWTONIAN REFLECTOR by Horne and Thornthwaite, of First-class Definition, 6½-inch Aperture, mounted on very steady Iron Pillar, Screw Motion in Right Ascension, and Declination Circles divided in brass, Battery of five Negative Eyepieces, one Transit do. and Barlow in separate box. Double Nosepiece to eye end.—May be seen and examined in the Observatory on application by letter only to A. R. Hunter, 15, Park Drive, Heaton, Bradford, Yorks. Price £28.

WANTED.—FIRST-RATE ASTRONOMICAL TELESCOPE, by Good Maker; cheap; about 9-inch Object-Glass.—Apply, R. M. Collingham, Heside, Hull.

Abonnement partant par la poste—un an, 15s. 6d.; six mois, 7s. 9d. Prix réduits pour les libraires et aux gares des chemins de fer. Un Numéro aux Bureaux, 25, Southampton Street, Strand, Londres, W.C.

LA SEMAINE FRANÇAISE.—"La Semaine Française has been brought out in London for the benefit of those English readers who may wish to study contemporary French from all points of view, instead of confining their reading to one particular Gallic print. It certainly merits success."—Graphic.

LA SEMAINE FRANÇAISE.—"The numbers before us are full of good things. . . . It will be far better for most than any one of the best papers published in Paris itself. We are much pleased with the character of it, and believe it will be highly valued in all those many households where French is understood. The printing is very well done."—Queen.

THE "HANSA"

Published since 1861 in Hamburg is the only independent professional paper in Germany, dedicated exclusively to Maritime Objects. Essays, Criticisms, Reviews, Reports, Advertisements, Notes) are kept upon the development of Maritime Affairs in every respect. Every second Sunday one Number is 40 or more Frequent supplements and drawings. Subscription at any time; preceding numbers of the year furnished subsequently. Once for the twelve months. Advertisements are a most secure spread by this paper; considerable assistance for 2, 5, 10 or more insertions. Business Office: Alle Reihe und Poststrasse, Hamburg, Alleinvertreter ist Inhaber W. v. Fenssen, M.D., Hamburg, Alexander Strasse 2.

NORTH BRITISH AGRICULTURIST

is the only Agricultural Journal in Scotland, and circulates extensively amongst Landed Proprietors, Factors, Farmers, Farm-bailiffs, and others interested in the management of landed property throughout Scotland and the Northern Counties of England.

The AGRICULTURIST has also a very considerable circulation in the Continent of Europe, America, Australia, and the Colonies.

The AGRICULTURIST is published every Wednesday afternoon in time for the evening mails and contains Reports of all the principal Scottish and Irish Markets of the week, besides Telegraphic Reports of those sold on the day of publication.

The Veterinary Department is edited by one of the leading Veterinarians in the country, and is invaluable to the breeder and feeder as a guide to the rearing of animals, and their treatment when labouring under disease.

Full Reports are given of the doings of the Royal Agricultural Society of England, the Royal Agricultural Society of Ireland, the Highland and Agricultural Society of Scotland, the Scottish Chamber of Agriculture, and all the principal Agricultural Associations throughout Great Britain and Ireland.

For Advertisers addressing themselves to Farmers a better medium does not exist.

Price 3d. By post 3½d. Annual Subscription payable in advance, 12s. Office—377, High Street, Edinburgh.
Post-Office Orders payable to Charles Anderson, Jun., Edinburgh.

EYE-SIGHT

GOOD AND BAD.

R. BRUDENELL CARTER, F.R.C.S.

Ophthalmic Surgeon to St. George's Hospital, &c.

WITH ILLUSTRATIONS.

"Both Prof. Helmholtz and Mr. Brudenell Carter's books aim at wide usefulness, and in a popular form, and both are notable and excellent in their way. . . . In *Mr. Brudenell* more recent book the important theme which has been so gracefully and eloquently adv Prof. Helmholtz is followed up into its practical and serviceable applications. The proc light, and the structure and functions of the eye, are in the first instance explained, done in language so simple and clear that the subject is brought within *the easy appre* persons of the most ordinary intelligence. . . . Mr. Carter's volume, although of small and unpretentious aspect, is really a most serviceable exposition of the principles concerned in the exercise and preservation of the human organs of sight, and of the sound vision."—*Quarterly Review.*

SCIENTIFIC WORTHIES

XVIII.—JAMES CLERK MAXWELL

Born June 13, 1831; *Died November* 5, 1879

WE have already (vol. xxi. pp. 43 and 317) said so much on the life and work of the late Prof. Clerk Maxwell, that in presenting his portrait as one of our Scientific Worthies, little more is necessary than to refer to the leading facts of his life. Born on June 13, 1831, he was the son of John Clerk Maxwell of Middlebie, a scion of a well-known Scottish family, the Clerks of Penicuick. When James was only eight years of age, he lost his mother, after which his father led a retired life, devoting himself to the care of his estates and of his son. The latter was educated in the first instance at the Edinburgh Academy, where in 1845 he gained the Academical Club Medal for Geometry, and the Silver Medal for Mathematics in 1847. A visit to William Nicol at this period was a marked event in his life, leading him, with apparatus of his own construction, to make observations on polarised light. A pair of prisms presented to him by Nicol were treasured by him throughout life, and three weeks before his death they were deposited in one of the show-cases of the Cavendish Laboratory.

After leaving the Academy, Maxwell, to quote the words of Prof. Tait (NATURE, vol. xxi. p. 317), "spent the years 1847-50 at the University of Edinburgh, without keeping the regular course for a degree. He was allowed to work during this period, without assistance or supervision, in the Laboratories of Natural Philosophy and of Chemistry: and he thus experimentally taught himself much which other men have to learn with great difficulty from lectures or books. His reading was very extensive. The records of the University Library show that he carried home for study, during these years, such books as Fourier's *Théorie de la Chaleur*, Monge's *Géométrie Descriptive*, Newton's *Optics*, Willis' *Principles of Mechanism*, Cauchy's *Calcul Différentiel*, Taylor's *Scientific Memoirs*, and others of a very high order. These were *read through*, not merely consulted." In October, 1850, Maxwell went to Cambridge, entering at Peterhouse. Soon after his entry at Peterhouse, however, in December, 1850, he migrated to Trinity, where he found spirits of tastes similar to his own in the matter of physical research; here he soon became a leader among his fellows. In 1854 he came out Second Wrangler, and was bracketed as First Smith's Prizeman. In 1855 Maxwell became a Fellow of Trinity, and in 1856 he obtained the Professorship of Natural Philosophy in Marischal College, Aberdeen. To quote the memoir by Mr. W. Garnett in NATURE, vol. xxi.:—"In 1858 he married Katherine, a daughter of Principal Dewar of Marischal College, thus vacating his fellowship at Trinity. In 1860 he succeeded Prof. Goodeve as Professor of Natural Philosophy and Astronomy in King's College, London, but after the death of his father he retired in 1865 to his estate in Scotland, where he subsequently carried out his father's plans for completing the house and offices at Glenlair. In 1871 he was invited by the Senate of the University of Cambridge to accept the Chair of Experimental Physics which had just been created, and on October 25, 1871, he delivered his inaugural lecture as Professor of Experimental Physics in the University of Cambridge. At first the most important part of his work consisted in arranging the details of the Cavendish Laboratory which the Duke of Devonshire had offered to present to the University, and the building of which was personally superintended by Prof. Maxwell from first to last. The whole of the arrangements which render the Cavendish Laboratory so admirably adapted for Physical investigations, are due to the care and forethought of Prof. Clerk Maxwell. When the building had been completed and formally presented to the University, the Duke of Devonshire further signified his desire to provide it with a complete equipment of apparatus, and all this was procured under the personal supervision of the Professor. In 1872 he was elected Honorary Fellow of Trinity College, Cambridge."

During the winter of 1878-9, Prof. Clerk Maxwell's health began to give way, and with some transient gleams of hope he gradually sank, dying on November 5, 1879. He received many honours during his lifetime; he was a Fellow of the Royal Society, LL.D. of Edinburgh, and D.C.L. of Oxford; Honorary Member of the American Academy of Arts and Sciences, the American Philosophical Society, and the New York Academy of Sciences; Corresponding Member of the Imperial Academy of Sciences, Vienna, and Associate of the Amsterdam Royal Academy of Sciences.

In 1860 the Rumford Medal of the Royal Society was awarded to Prof. Clerk Maxwell "for his Researches on the Composition of Colours, and other Optical papers." In his address on the presentation of the medal, Major-General Sabine alluded to Prof. Maxwell's calculation showing the connection of the "mechanical strains to which elastic solids are subjected under certain conditions with the coloured curves which these solids exhibit in polarised light."

To Clerk Maxwell's private character, to the position he unobtrusively took as a Christian, to his qualities as a poet and humorist, and to the varied work he has accomplished, it is scarcely necessary again to allude here; all these points will be found clearly brought out in the articles by Prof. Tait and Mr. Garnett above referred to. Nor is it necessary to repeat here the list of his principal papers and publications, and the great and important additions which Clerk Maxwell made to the sum of scientific knowledge, or the light he shed on the principles of the departments of science which he specially cultivated. Besides the references already given we would commend the reader who desires to have a fairly complete notion of the value of the work of the remarkable man whose portrait we give to-day, to the articles by Prof. Tait on Clerk Maxwell's "Electricity and Magnetism," vol. vii. p. 478, "Matter and Motion," vol. xvi. p. 119, and the numerous papers by Maxwell himself scattered through the volumes of NATURE.

DR. SIEMENS ON TECHNICAL EDUCATION

FEW can read the address of Dr. C. W. Siemens to the Midland Institute, which appears in another place in our columns (p. 619), without admitting that of

Digitized by Google

all living men Dr. Siemens has the best right to speak upon the relations between scientific education and the scientific industries. Himself a product of the educational system of Germany, and one of the foremost, if not in his own line the foremost, of scientific men in the industrial world, and in the land of his adoption, he yet uses no unmeaning terms when he tells us that the particular form of technical education afforded by that characteristic institution, the German Polytechnicum, "is certainly inapplicable to the condition of things which we find in this country."

The argument with which Dr. Siemens enforces this view is, so far as we are aware, a novel one from the educational point of view. He assumes frankly and without disguise that in any industry which is, like the railway system of Germany or our own telegraphic system, a Government monopoly, there is essentially a tendency to discourage improvements or any thing savouring of novelty or innovation. He also assumes that the system of "polytechnic" education fosters a like tendency, inasmuch as he thinks that, as administered in Germany, this system turns out students destitute of originality, and dogmatically persuaded that the particular machines or processes they have studied in the Polytechnicum are embodiments of perfection proved and established like propositions in Euclid. From these two premises the inference logically follows that although the Polytechnicum may be all very well for turning out young men fitted for Government appointments in a country where railways, mines, and factories are State establishments, such an institution is inappropriate in a country like England.

There is doubtless much force in this position, though the contrast between industrial conditions in Germany and England is hardly fairly represented by so sweeping a generalisation. If in a land of strong tendencies toward monopolism and conservatism the system of technical education has taken a similar bias, we should be disposed to argue that a complete system of technical education would, in a country where industrial enterprise is freer, tend toward a freer development.

On the other hand, Dr. Siemens sees plainly the inherent badness of the condition of things in England, where technical education has so long been neglected. He condemns *in toto* the old system of binding a lad to an apprenticeship of seven years' drudgery and mechanical routine, causing him, as such a system does, to give up thinking altogether; and is in favour of a much shorter term of pupillage.

Though he is not very explicit on the point, it is not difficult to gather the general drift of Dr. Siemens' views as to what system he would adopt in preference to the method of the German Polytechnic Colleges. Firstly, he would have science-teaching systematically incorporated in the educational curriculum of every school in the manner in which we have for years advocated, and in which Sir John Lubbock and many others have advocated it. He would also have science taught by practical work in chemical, physical, and mechanical laboratories attached to the schools. In the case of the industrial classes he would have mathematics and natural science taught to all lads before the age of fourteen, and would fix that as the *minimum age* at which they should be admissible to work in mines or factories. Were this done, he thinks a three years' apprenticeship would be amply sufficient to learn any mechanical trade; and he would lay upon the employer the responsibility of seeing that during this term the apprentice spent his evenings and his Saturdays in diligent attendance at some technical or technological class where the principles underlying the operations of his business would be taught him.

We cannot too heartily endorse this last suggestion, which is now the more appropriate when not only in the metropolis but in all our chief towns and cities such classes for pure and applied science are being held under the auspices of the Science and Art Department and of the City and Guilds' Institute.

Another point on which Dr. Siemens speaks with weight is the importance of providing an adequate supply of trained teachers. Those who know the history of the attempts to render the teaching of the science classes under the Science and Art Department of greater efficiency, will heartily unite in the satisfaction expressed by Dr. Siemens concerning the reforms now in progress by which the Royal School of Mines and its associated science classes will be reorganised and developed into a Normal School of Science. The neglect and apathy of previous Governments have been indeed deplorable; but it is to be hoped that the greatest of the acknowledged defects of the national system of science-teaching are now in a fair way to be efficiently remedied.

Dr. Siemens points out that while laboratory work in schools is necessary it is comparatively inexpensive, being elementary in character. But for the efficient training not of teachers alone, but of students who have advanced beyond first principles, the delicate and elaborate appliances of exact science are more than ever essential, and for that reason "very complete laboratories are of great importance at the universities and superior colleges, where exact science and independent research take the place of mere tuition of first principles." We trust these words will not be lost in the places where they are most needed. When we look at the large and complete equipment of the mechanical, physical, and chemical laboratories of the colleges and universities to be found in every large town in Germany, France, and Switzerland, and compare them with the utterly shabby and insignificant dens which go by these names in the science colleges of Newcastle, Bristol, and Leeds, we feel that by no means the least important point of Dr. Siemens' discourse is the paragraph we have quoted above.

The concluding remarks, in which Dr. Siemens alludes to the Electrical Exhibition in Paris as pointing the moral of the inevitable changes and improvements which are continually invading every branch of industry cannot fail to impress many whose experience will confirm the truth of the observation. The plain fact remains that in the race of industrial improvements England cannot afford to stand still. And if the Continental nations have in some respects stolen a march upon us in these last years, it is not yet too late to organise and develop a system of technical education of our own adapted to our own special industrial conditions and needs.

RECENT ORNITHOLOGICAL WORKS

The Ornithological Works of Arthur, Ninth Marquis of Tweeddale, F.R.S., etc. Reprinted from the Originals by the desire of his Widow. Edited and Revised by his Nephew, Robert G. Wardlaw Ramsay, F.L.S., etc., Captain 74th Highlanders. Together with a Biographical Sketch of the Author, by William Howard Russell, LL.D. 4to. Pp. i-lxiv., 1-760. (London: For Private Circulation, 1881.)

Ornitologia della Papuasia e delle Molucche, di Tommaso Salvadori. Parte seconda. 1 vol. 4to. 706 pp. (Torino, 1881.)

THE very handsome volume, in which the works of the late Marquis of Tweeddale have now been collected and published, forms a fitting monument of the labours of one of the best ornithologists that this country has ever produced, and its utility to working naturalists cannot be doubted. No one who knew the author of these memoirs will be surprised at the new aspect which is thrown upon his life by the publication of the biographical sketch which Dr. Russell has contributed, though to scientific men Lord Tweeddale was chiefly known as a laborious ornithologist and a thoroughly sound writer and critic; but from the volume now before us we read the highest testimony to his qualities as a soldier, and receive evidence that the same thoroughness which characterised his scientific work was also prominent throughout the whole of his military career. His first ornithological paper appears to have been published in 1844, and was a carefully-written essay; and then for the space of twenty-two years nothing bearing on his favourite study appeared from his pen. His biography, however, shows that during this lapse of time he was completely occupied with his military duties, serving throughout the Sutlej campaign, and later on taking part with the Guards in the memorable Crimean War; and even at this distance of time it is refreshing to read the clear and vigorous criticisms which his keen perception enabled him to make at that period on the conduct of military affairs in the East. Retiring from active service in 1863, he appears to have from that time devoted himself to the pursuit of his favourite science, and until his death, in 1878, he worked with unflagging zeal at the ornithology of the Indian region, amassing one of the grandest collections of birds which has as yet been seen in any country, and forming a library unsurpassed for its completeness in ornithological literature.

To his nephew, Captain Wardlaw Ramsay, who has inherited his scientific tastes, the late Marquis bequeathed his magnificent library and collection, and the pious duty has devolved upon him of editing a complete edition of his uncle's memoirs, at the request of Lady Tweeddale, who has hereby raised a monument to her husband's memory which will keep the latter green in the minds of ornithologists for many a long year to come. Many of Lord Tweeddale's most important observations were contained in letters or short papers to various journals, and there was always a possibility of their being overlooked; but by the publication of the present volume, with its complete indices and cross-references supplied by the editor, there will be no such risk in future. Lord Tweeddale's life forms a pleasing picture of what an English nobleman can do for science, if only his intelligence leads him in that direction; and many who are living can remember with pleasure the days spent beneath the hospitable roof at Chislehurst, where Lord Tweeddale was always glad to welcome any scientific visitors, for his love for science took a deeper turn than the mere following of his own particular branch of ornithology, and he always displayed an interest in every branch of intellectual study.

The perusal of his many excellent essays only deepens the regret that was felt by every one at the time of his decease, that a life only in its prime, and capable of doing so much good in every way, should have been prematurely closed.

In our notice of the first volume of Prof. Salvadori's work (NATURE, vol. xxiii. p. 240) we gave some account of the scope and origin of this great undertaking, and of the extensive materials upon which the author had based it. It is with great pleasure that we now chronicle the issue of the second volume, and record the announcement that the third, which will complete the work, is far advanced in preparation.

It will be recollected that the rich collections made by the Italian travellers D'Albertis and Beccari during their several expeditions into New Guinea and the adjoining islands, all of which came under the examination of Prof. Salvadori, were the "moving cause" of the present undertaking. Besides amassing numerous minor novelties and whole series of little-known species, these industrious explorers were the original discoverers of four new birds-of-paradise, several new pigeons and parrots of splendid plumage, and the large and fine bird-of-prey named *Harpyopsis Novæ-Guineæ*. It was an obvious, though by no means light and easy task, to weave together the numerous papers and memoirs in which the different collections had been described into a uniform series, and to supplement it by summarising what was previously known of Papuan ornithology. This is what Prof. Salvadori has undertaken, and the result will be an excellent work upon a subject with which our previous acquaintance was of a very fragmentary description.

In his first volume, published in 1880, Prof. Salvadori treated of the *Accipitres*, *Psittaci*, and *Picariæ* of the Papuan sub-region. In the second volume now before us the numerous army of *Passeres* comes under consideration, and swells its size to 706 pages. The plan of treatment pursued is exactly the same as that which we have described in the case of the first volume. Every species is fully and fairly described, its complete synonymy is given, and a detailed list of the specimens examined from the various localities over which the species is spread is added.

It appears that the Royal Academy of Sciences of Turin, which published Prof. Salvadori's first volume as one of their "Memorie," have unfortunately not found it convenient to adopt the same course as regards the second. The author is therefore compelled to appeal to his brother ornithologists to subscribe for copies of the second and third volumes of his most meritorious work, in which we are sure he will receive every sort of support. Few special works of the present day have been so well planned, or so thoroughly carried into execution.

OUR BOOK SHELF

Deschanel's Natural Philosophy. Edited by Prof. J. D. Everett. Sixth edition. (Blackie and Son, 1882.)

PROF. EVERETT'S admirable adaptation of "Deschanel's Natural Philosophy" is so well known as a text-book that it needs no commendation from us. We heartily welcome this sixth and greatly improved edition. Amongst the new items we notice that the chapter on thermodynamics has been amplified and re-written; and other parts of the book devoted to heat have also been improved, particularly those relating to the apparent minimum density of water, and to conduction of heat. We notice also a useful note on the mathematical treatment of the periodical variations of underground temperatures. The section dealing with electricity and magnetism has also been greatly improved. The elements of electric testing by Wheatstone's bridge and resistance coils are now included. The modern dynamo-electric machines and such recent inventions as the electric pen and the induction-balance are described. Rowland's experiments on electric convection-currents, and Planté's secondary battery are also mentioned; though it appears to us that a slight slip of the pen in the paragraph dealing with Planté's researches his "rheostatic machine," which is in reality a compound condenser of mica plates, is described as a species or commutator (like that of Müller) for his secondary batteries. There is another slip in the paragraph on the use of the galvanometer for measuring transient currents, for it is stated that the quantity discharged through the galvanometer is proportional to the swing of the needle, whereas by the well-known ballistic formula of Maxwell, it is proportional to the sine of half the angle of the first swing. These are however minor points. In the section on Light and Sound little has been changed; the more recent measurements of the velocity of light, and the phonograph, being the most important additions. It is a pity that in the optical formulæ the editor does not use the same notation as in the accepted Cambridge text-books. The problems, which in former editions were lumped together at the ends of the book, are in this new edition placed at the ends of the separate volumes, a change which is a great boon to teachers and students who find it most convenient to buy the separate parts. Why the date of 1882 should be put upon a work which appears in October, 1881, is one of the mysteries of publishing which lies beyond the pale of scientific criticism.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts.

No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

The Struggle of Parts in the Organism

As the Duke of Argyll does not appear to have quite understood the meaning which I intended to convey in the paragraph of my review to which he refers, I should like to state that meaning a little more explicitly. This I should have done in the first instance had I not shared the feeling which he expresses, that "a purely scientific journal" is not an appropriate place in which to discuss the relations of science to theology, and I shall now hope to show that in my review I did not transgress the limits of any such debatable ground.

My remarks were limited to the "Argument from Design as elaborated by the natural theologians of the past generation," the material of which was furnished by "the endless number and complex variety of those apparently purposive adaptations of structures to functions which are everywhere to be met with in organic nature." By this limitation I intended every one conversant with the writings of these theologians to understand that I alluded only to the Argument from Design as founded by the school of Paley, Bell, and Chalmers, and amounted to inferring that particular instances of adaptation, so many separate pieces of evidence pointing to "operations of special design." This is the frame of mind which I conceive Mr. Darwin's writings to have overthrown, for these writings have shown that in nature, as we have a general law whose operation is present only to produce most of the adaptations previously ascribed to "scientific teleology," and I did so because it made it clear in the full sense of the term, a scientific theory: certain facts or results were observed, and of these results the true cause was inferred. Therefore the endeavour to explain causation of special mechanisms in organic nature admits of being discussed in the pages of a scientific journal it is as purely a scientific hypothesis as is that of selection.

But the Duke of Argyll clearly attaches to the word "design a much wider signification than that which I supposed myself rationally assigned to it. For he uses the term to denote, in the most sense, and says: "There are many minds—including some of most distinguished in science, who not only fail to see any tradition between evolution and design, but who feel that the doctrine of evolution and the facts on which it is founded supplied richer illustrations than were ever before supplied the operation of design in nature," &c., &c.

Here and elsewhere the Duke clearly alludes to the question of Theism, or of Mind as the First Cause, and as the narrower one of this or that particular mechanism as the result of immediate and special design. Now although in this larger sense, or the doctrines that behind all the laws to scientific inquiry (special mechanisms, physical causes, general laws) there is "Mind and Will" as the ultimate cause all things—teleology in this sense is a general theory of the which it does not fall within the scope of scientific method examine. In contradistinction to the cruder teleology of which, as I have said, may properly be called "metaphysical"—if we use these terms as they are used by Lewes to denote respectively a theory that is not may be called "metaphysical"—if we use these terms as they are used by Lewes to denote respectively a theory that is not fiable (or the reverse) and a theory that is not. The advocate thought that the existence of a designing Mind in nature be proved by a purely inductive method; Mr. Darwin has shown that such is not the case; therefore this system of ology is a scientific system, and, like many other theories scientific class, it has had to yield to fuller knowledge there remains the metaphysical theory of an ultimate pervading all nature and blending into one harmonious what the Duke calls the "combination and co-ordination physical causes"; and this theory, I quite agree with him possible amount of discovery concerning the physical natural phenomena can affect," either by way of proof disproof. But this has nothing to do with the special between Darwinism and "the argument from design as rated by the natural theologians of the past generation therefore I shall not discuss the merits of the theory in the columns.

GEORGE J. ROMANES

"The Micrococcus of Tubercle"

AN article on "Disease Germs," by Dr. W. B. Carpenter, in the current number of the *Nineteenth Century*, contains the following:—"Another line of inquiry which has obviously the most important bearing upon human welfare is the propagation of the micrococcus of tubercle by the milk of cows affected with tuberculosis, a question in regard to which some very distinct facts have been brought before the Medical Congress by a promising young pathologist"—naming myself, and for which I am sufficiently grateful to a veteran in science for so complimentary if not altogether accurate reference to my work. What I did say at the recent Medical Congress, and at much greater length in a small volume entitled "Bovine Tuberculosis in Man" (London, 1881)—Dr. Carpenter will see it, I think, among his books—was not anything about "the micrococcus of tubercle," but about a variety of somewhat technical morphological details in respect to which the cases of tuberculosis in man resembled the bovine species. "Pearl disease" of the bovine species. I also named but in less than a page at the end of my essay to show the

Digitized by Google

was the issue between my view of tuberculosis communicated from the cow and the view which Dr. Carpenter has been expounding, and I hope you will have room for the passage:—

"The doctrine of a tuberculous virus was stated by Klebs in 1868, and has been advocated by him, as well as by Colnheim, in recent writings. In its latest form this doctrine asserts the existence of a specific minute organism to whose agency the infection is due. The minute organism is called by Klebs *Monas tuberculosum*. The method of proof which I have followed in this work makes it impossible that the infective agency of a minute organism should in any way come into my view of the communication of bovine tuberculosis to man. I have rested the whole case upon certain minute identities of form and structure in the infected body, due to the mimicry of infection. Among other points there were the leaf-like and cord-like outgrowths of the pleura and peritoneum, these being the early stages of the lentil-like or pearl-like nodules and their connecting threads; the lymphatic glands, with distinct nodular formations in their substance; the lungs, with smooth-walled closed vomicæ or with encapsuled nodules. In the new formations generally there was a particular pattern of microscopic structure, in which giant-cells and epithelial-like cells figure largely, and there was a relatively high degree of vascularity. In all these points the disease in man is a mimicry of the parent disease in the bovine animal. That mimicry is not only in single features, but it is of the whole disease. It is possible to conceive of the juices and particles of the primarily diseased body acquiring a kind of spermatic virtue which gave them the power to communicate the specific disease as a whole and in all its several manifestations to another body in which they should happen to lodge. But it is hardly possible to think of a neutral living organism being charged with the power of conveying so complex details of form and structure from one body to another" ("Bovine Tuberculosis in Man," pp. 103, 4).

25, Savile Row, W., October 24 C. CREIGHTON

A Kinematical Theorem

PROF. MINCHIN'S Theorem in NATURE (vol. xxiv. p. 557) may be proved easily by considering the motion as due to the rolling of one closed curve on another back into its first position, their lengths being of course commensurable. If you measure y for the rolling curve from the straight line which forms the envelope, and x along that line, then the differential of the area between the envelope and the fixed curve is easily seen to be $y\,dx + \frac{1}{2}y^2\,dw$, where dw is the angle turned through by the rolling curve, and is equal to ds multiplied by the sum of the curvatures at the point of contact, which we shall call σ. The summation of the former part is a multiple of the area of the rolling curve, and therefore the same for all lines; that of the latter is half the moment of inertia of matter distributed over its perimeter with density σ, about the line in question. The result is therefore the well-known property of equi-momental ellipses. Similar reasoning, with the use of the property of the centre of inertia of a system, leads to the further result that when the perimeter of the envelope is of constant length, the line touches a circle, and different values of the constant correspond to concentric circles. In the same way by a property of the centre of inertia we may also prove immediately the known theorem that when the area traced out by a point is constant, the point lies on a circle, and different values of the constant correspond to concentric circles; and we may extend it to areas traced on a sphere. JOSEPH LARMOR

54, Antrim Road, Belfast

IF Prof. Minchin will refer back to the *Bulletin des Sciences Mathématiques et Astronomiques* for August, 1878, he will, I think, find in a paper by M. Darboux the theorem stated by him under the above title in NATURE, vol. xxiv. p. 557.

C. LEUDESDORF

Pembroke College, Oxford, October 21

"The Dark Day"

REFERRING to the account of the phenomenon in New England on September 6 last (NATURE, vol. xxiv. p. 540), and in Mr. Harding's letter (p. 557), let me refer your readers to a succinct account of the occurrence on May 19, 1780, which they will find in Webster's Dictionary, "Explanatory and Pronouncing Vocabulary of the Noted Names of Fiction, &c." In *Public Opinion* (June 4, 1881) there is an account of a precisely similar occurrence on the morning of Sunday, November 8, 1819, known, it is remarked, as the "Phenomenon of 1819." The account of this phenomenon is very explicit, and the details furnished correspond so closely with the event of May 19, 1780, that a doubt might be felt whether there had been two such days, or whether there had not been some mistake made in regard to the date given. I wrote to *Public Opinion*, making inquiries (see *Public Opinion* of June 11, 1881, p. 755), but no reply has hitherto appeared to my inquiries. I may observe that the year 1819 would not coincide with any one of the sun-spot cycle of eleven years from 1780 to which the New York *Nation* refers. A. TREVOR CRISPIN

6, Melbury Terrace, Harewood Square, N.W., October 22

OWENS COLLEGE SCIENCE AND LITERATURE FELLOWSHIPS

THE first award of these Fellowships, of the annual value of 100*l.* each, which are intended to encourage original investigation, was made on Friday last by the Council of the Owens College. These are remarkable as being the only fellowships given in any University or College in the United Kingdom solely for the encouragement of research. They are not awarded on the results of examination, but after consideration of documentary or other evidence. Every holder of a fellowship is expected to devote his time to the prosecution of some special study, and before the close of the year to give evidence of progress by the preparation of a thesis, the delivery of a lecture, or the completion of some research. He may also be called upon to render some service to the College either by acting as occasional examiner or by giving instruction by lectures or otherwise to the students.

Of the thirty candidates four gentlemen were elected to Fellowships. Of these one is awarded to Mr. Alfred Sidgwick, B.A. of Lincoln College, Oxford, in the Department of Logic; two were awarded in the Department of Chemistry, namely, one to Dr. Bohnslav Brauner, of the University of Prague, who has already published several papers on original subjects, some from the laboratory of the Owens College; and a second to Mr. Harry Baker, Dalton Chemical Scholar of the College, who has likewise published several papers in the *Journal* of the Chemical Society. These two gentlemen will continue their researches, devoting the whole of their time to original investigation. In the Department of Biology an award has been made to Mr. H. Marshall Ward, B.A., F.L.S., of Christ College, Cambridge, at one time a demonstrator in the Owens College, who has recently distinguished himself as Government cryptogamist in Ceylon, in an investigation of the cause of the coffee disease.

THE AGE OF THE IGNEOUS ROCKS OF ICELAND

DURING a recent visit to the south-west part of Iceland, one or two points connected with the general geological structure of the island came under my observation, which I do not remember to have seen noticed before, and which seem to me to be of sufficient interest to be put on record. It is well known that the rocks of the island are of very different ages, some going back to the Miocene period, while others are quite of yesterday's date. It is also perhaps a general belief that the volcanic forces may have continued to be more or less active from the time that the older Miocene basalts and tuffs were erupted down to our own day. I doubt very much whether there is any evidence to justify this conclusion, and will presently mention some of the facts which lead to a very strong suspicion that a prolonged period of repose supervened after the accumulation of the Miocene rocks, and before the eruption of the later lavas, &c., had begun. The Miocene group consists of a vast

Digitized by Google

series of basalt rocks with interbedded layers of palagonitic tuff, &c. These rocks, so far as my observations go, exactly resemble those of the Færöe Islands. The basalt-rocks are chiefly anamesites, but some are true basalts, while others are dolerites. But in the areas traversed by me I saw none so coarse-grained or so highly porphyritic as those which occur so abundantly in Strømöe, Österöe, and other islands of the Færöes. They form lofty plateaus, deeply gashed with gorges, and abruptly truncated, so as to present bold cliffs and precipices to the low grounds at their base, as in the case of the Esja near Reykjavik. Moreover, they appear to be developed chiefly in the maritime districts. Only a glance at these basaltic masses is needed to convince one that they are the mere fragments of what must once have been a most extensive plateau. The Esja, built up chiefly of comparatively horizontal beds of basalt, tuff, &c., rises to a height of nearly 3000 feet above the low tracts at its base. Nor can there be any doubt that these beds formerly stretched far away in all directions, and that they have since been removed by the various agents of denudation from the broad undulating low grounds, over which they may still be traced, sometimes continuously for many miles, at other times in sporadic hills and rising grounds which peer above the surface of the recent lavas by which they are surrounded. In short, the Miocene basalt-rocks of Iceland present precisely the same features as the similar rock-masses of the Færöes. Like the latter they probably formed at one time a wide elevated table-land, which has since been cut down and worn away—the lofty walls of the Esja, &c., serving to give us some idea of the enormous erosion that has taken place. Now all this vast erosion had been effected before any of the later lavas, agglomerates, tuffs, &c., in the south-west part of Iceland were erupted. In the region between Hafnarfjörd and Krísuvík the lavas have poured through old valleys in the Miocene rocks and spread themselves out over the highly denuded surface of the latter in the opener low grounds. In a word, it is evident that in the south-west part of Iceland a long interval separates the accumulation of the Miocene basalt-series from the eruption of the later volcanic rocks, and I incline to think that the same break in the continuity of volcanic action will be found to hold true for the rest of the island. I believe it will be found that there is no more connection between the display of volcanic activity in Miocene times and that of the present day in Iceland, than there appears to have been between the volcanic action which manifested itself in Scotland at such widely separated periods as those of the Lower Old Red Sandstone and the Carboniferous. Had there been more or less continuous volcanic activity in Iceland from Miocene times down to the present, we might well be surprised that the later volcanic masses are not much more considerable than they are. If we think of the time required for the removal by denudation of some 3000 feet of basalt-rocks, &c., over thousands of square miles, we must be prepared to admit that the volcanic forces cannot have been continuously active. Either they have not been so, or the denuding agents have far surpassed them in energy.

There is another point which interested me. I found that the whole of the south-west region had been glaciated before the eruption of the later volcanic series. The Miocene basalts are everywhere ice-worn and abraded; *roches moutonnées* are well-marked, and in many places glacial ruts and striæ are conspicuous. Glacial gravels and coarse boulder-clay are likewise sprinkled over the surface of the low-lying tracts. Between Reykjavik and Hafnarfjörd the glaciation is distinctly from south-east to north-west, and could not have been the result of any mere local glacier. The whole wide tract has been overflowed by a general *mer de glace*. And if this be the case with that part of Iceland which now enjoys the mildest climate, we may be sure that *the* rest of

The peculiar Diploxylon hich possess the outer cauges on some as characteristic of a Sigillarian stem, of Autun and St. Etienne, as they are In Great Britain, on the other hand, ons of specific details, our prevailing

the Lycopods and the Dadoxylons of the Devonian beds of North America. But what do we know of this earlier flora? Almost nothing. The remains of pre-Devonian plants now known are so obscure that little reliance can be placed upon them. Eophyton is rejected from the vegetable kingdom by Nathorst, and most of the other so-called Fucoids of the Palæozoic strata are of almost equally dubious nature. Where more definite forms of what may probably be Marine Algæ do occur they come too late in time to avail in the construction of the Palæozoic pedigree. Even the Liassic *Chondrites bollensis* of the Lias cannot be depended upon with absolute certainty. It is only when we reach the Tertiary age that we find the Delesseriæ and Halymenites in shapes that leave little room for doubting their true nature. Yet our French friends trust to these dubious objects as being real Fucoids, and as such, the ancestral predecessors of the higher Cryptogams of the Devonian and Carboniferous ages. So long as this ignorance and uncertainty remain, it seems to me that we cannot construct, with any degree of probability, the genealogical tree of Palæozoic plant life.

As to the many detailed conclusions arrived at by MM. Saporta and Marion, I will only refer to two or three statements in addition to the more important ones to which I have already called attention. Thus Mr. Gardner's abstract states that "eight still existing Diatoms have been discovered in British Coal." I thought that I had thoroughly exploded that fallacy in my Memoir, Part X. MM. Saporta and Marion conclude that Asterophyllites was a floating or procumbent plant allied to the Equisetaceæ, thus following M. Renault in separating it from Sphenophyllum, which the authors believe to be a Rhizocarp allied to Salvinia. I see no ground whatever for these conclusions. They further consider that some of his Calamariæ (Equisetaceæ) were heterosporous. They arrive at this conclusion from my discovery that *Calamostachys Binneyana*, which I believe to be a fruit of an Asterophyllitean plant, was a heterosporous Strobilus; but I wholly demur to the idea that either the plant or the fruit was Equisetaceous.

For the reasons above given, I doubt whether even my valued friend the Marquess Saporta, highly accomplished as I know him to be, will be able to "make clear the precise lines through which the evolution of the one from the other [*i.e.* the Phanerogams from the Cryptogams] has been accomplished."

Owens College, Manchester, October 14

THE INTERNATIONAL EXHIBITION AND CONGRESS OF ELECTRICITY AT PARIS[1]

V.

THE labours of the jury are now finished, and the distribution of medals took place on October 21 at the Conservatoire des Arts et Métiers. It is understood that they have been somewhat liberal in their distribution of honours, and have endeavoured to make things pleasant all round. Indeed the time allotted to them for investigation being postponed for a week at the beginning, and afterwards cut short by a week at the end, was quite insufficient to settle the burning question which is the best of all the electric lights.

The diploma of honour (*diplôme d'honneur*), which is the highest award of all, has been voted to Dr. Werner Siemens, Sir William Thomson, Mr. Edison, M. Gramme, Prof. Graham Bell, Prof. Hughes, Prof. Pacinotti, Prof. Bjerknes, M. Gaston Planté, M. Baudot, and M. Marcel Deprez, the last-named being the inventor of a system of distribution of electricity which has found much favour in Paris. M. Baudot is the inventor of a multiple printing-telegraph. The Exhibition has been announced to close on November 15, but there is some talk of a later date.

[1] Continued from p. 589

During the last week a body calling itself the Réunion International des Électriciens has been holding meetings in a room granted for the purpose in the Exhibition building. It is understood to be mainly composed of persons who felt slighted at not being appointed members of the Congress, and are determined to have a little congress of their own; but their movements have not attracted much public attention.

As this will be our last article, we will endeavour to supplement our previous accounts by some information on what must be regarded as the most important of all the objects in the Exhibition, namely, the machines which generate the electricity. Those which have permanent steel magnets are few in number, and the only large ones are the machines of De Meritens. These usually give alternating currents, but can be made to give direct currents by a change in the connections. The principal type contains five Gramme rings mounted on the same axis, each of them surrounded by eight horseshoe steel magnets with their feet inward. The introduction of the Gramme ring is the chief difference between this machine and the old lighthouse machine of Holmes. The great bulk of the machines in the Exhibition are dynamos, in which the whole current produced passes through the coils of the field magnets, and a large proportion of them are of the Gramme type, generally with one pair of straight massive field magnets arranged in one line above the ring, with a pair of like poles near together close to the ring, and with another similar pair below of opposite polarity to the first pair. The ring thus revolves between two very strong poles outside it, and massive iron pole pieces are usually employed, so shaped as to embrace a considerable arc of the ring. These are the machines for direct current. In the alternating current Grammes, the ring is generally broadened out into a hollow cylinder whose length is as great as its diameter. Sometimes this revolves between four external pole pieces attached to electro-magnets, and sometimes it is fixed, while four broad electro-magnets radiating from the common axis revolve within it. In some examples a separate exciter giving a direct current is mounted on the same stand and on the same axis.

The three firms of Siemens at Berlin, Paris, and London have a very large and diversified collection, partly historical, partly representing the commercial demands of the present day, and partly embodying their latest ideas for future improvement. The prevailing pattern is the well-known Siemens direct acting machine, in which an armature in the form of a cylinder, about three times as long as it is broad, rotates between two sets of pole-pieces, one above and the other below, of opposite polarity produced by the action of four straight flat and massive electro-magnets. The coil of the armature is wound, as nearly as the presence of the axle permits, in planes containing the axis, so that the wires cross one another at all angles at the two ends.

The most remarkable novelty that struck us in going over their collection was a machine in which two armatures consisting of cylindrical iron cores, each inclosed between four longitudinal segments of copper, revolve within two hollow cylinders of iron, which are the poles of a composite magnet, so that each armature is surrounded by a pole of one name, while opposite polarity is induced in the outer part of the iron core. The lines of force thus radiate from the common axis with complete symmetry, and the longitudinal coppers cut these lines at right angles in every position, so that the electromotive force in each copper remains constant as the armature revolves.

A peculiar adaptation of the ordinary Siemens armature has been made by Mr. Edison. The conducting portion of his armature consists of bars and disks. The bars form the outside of the cylinder, and the disks, with mica between for insulation, are built up into two solid masses which form the ends. The intervening portion is occupied by the core, which consists of a thousand very thin disks of iron separated by oil paper. The course of the current is nearly the same as in the armature, being first along a bar, then across another disk back along an opposite bar, then across another disk, and so on. The ends of the bars are disposed on helical curves at the two ends of the cylinder, each having two convolutions. The object of having excessively thin iron plates is to promote rapid polarisation and to avoid the formation of induced currents in the iron. This monster machine has only recently arrived, and is not yet ready for action. Its size (which, as well as to that of a smaller machine, the description applies) is about four feet long by about diameter. It has two straight and very long field magnets which are actuated by a branch of the main current machine.

A very common pattern of machine for short currents, which one sees under various names, has a number of flattish cylindrical coils disposed in a circle fashion like the holes of a sieve, and revolving in close fashion between pairs of fixed cylindrical field magnets. More massive appearance, the number of pairs of fixed magnets being equal to the number of armatures.

There are also some direct current machines of novel construction. They can be distinguished by having a commutator of many segments on which the brushes bear to collect the currents, while the alternating machines take off their currents from two insulated rings which are not divided in any way.

Last Saturday evening there was a special gala at the Opera House in honour of the Electrical Congress, admission being by presentation ticket. In addition to the ordinary operatic performances there was a specially stilted poem in celebration of the achievements of the city, which was read between two of the pieces by an eminent comedian; and the whole performance was wound up with a grand chorus calling on the earth to light up. Preparations had been made for illuminating the house by electricity, but they were far from complete, and gas was decidedly in the ascendant. The only place where the telephonic transmitters are bestowed was recognised, there being a wooden screen about ten feet high and six feet long on each side of the promenade box.

We stated in a previous letter that a committee of jurors had undertaken some quantitative experiments on the machines and lamps. These are still going on, and will probably be continued till the Exhibition closes.

The chief practical result of the Congress has been the agreement to adopt the British Association system of units, and we understand that Prof. Everett's book, which is the recognised exposition of this system, will be immediately translated into French, German, and Italian.

THE IRON AND STEEL INSTITUTE

ONE of the most interesting features connected with the recent meeting of the Iron and Steel Institute was the fact that the Arsenal authorities abandoned at last the official reserve which has so long been complained of, and descended into the arena of professional discussion by reading papers on the manufacture of ordnance, projectiles, small arms, and gun-carriages, and submitting them to public criticism. We must specially congratulate Col. Maitland, the present superintendent head of Woolwich Arsenal, on having had the courage to take this step. His paper on the Metallurgy and Manufacture of Modern British Ordnance was very interesting. Its production also was well timed, coming at a period when the confidence of the public was sorely

ably shaken in the management of the Royal Arsenal, by the bursting of the *Thunderer's* 38-ton gun. Col. Maitland reviews in succession the early history of Steel *versus* Iron, the successive improvements in the manufacture of gunpowder, the processes of the manufacture of the iron and steel, the building up of the gun, and the boring and rifling of the barrel. The paper concludes with a description of some of the special tools and furnaces in use at the Arsenal. As regards the question of powder, it is satisfactory to find from an official utterance that the problem of the proper action of gunpowder is at last thoroughly understood. On this point the author states, "With the large slow-burning powders now used, long heavy shell move quietly off under the impulse of a gradual evolution of gas, the pressure of which continues to increase till the projectile has moved a foot or more; then ensues a contest between the increasing volume of gas, tending to raise the pressure, and the growing space behind the advancing shot tending to relieve it. As artillery science progresses, so does the duration of this contest extend further along the bore of the gun towards the great desideratum, a low maximum pressure long sustained." To this last sentence we call particular attention, for in the attainment of this object by our powder manufacturers lies the whole possible development of the power of artillery. When the author uses the words *low* maximum pressure, we take it that the expression must be understood in a relative sense only, and that the maximum pressure should not be high as compared with the mean; what is in reality the great desideratum is as high a maximum pressure as is consistent with the strength of the gun, sustained throughout the entire length of the bore. How far this object is from being attained at present can be seen at a glance from the shape of even the most modern heavy gun, which is very thick at the breech and dwindles down to almost nothing at the muzzle, showing that the pressures at the breech are still far from being sufficiently sustained. The problem here is more one for powder-makers than artillerists. The latter can but indicate what is wanted. It seems from *à priori* grounds impossible to expect that the solid pebble powder now in use, burning as it does from the surface to the centre, can ever give off the increasing volumes of gas wanted in order to fill up the spaces behind the advancing projectile, and thus maintain the pressure. It is, we believe, no secret that the results attained with our home-made powders are inferior to those furnished by the perforated prismatic powders made in Germany and Russia.

In dealing with pure metallurgical processes Col. Maitland made a great mistake in not making himself acquainted beforehand with the name of the inventor of the process of making steel adopted at the Royal Arsenal. Nearly two pages of the paper are taken up with a description of the process invented by Dr. Siemens, which is described in detail without any reference to that distinguished engineer, so much so that any uninitiated person reading the paper would have inferred that the process was peculiar to the Royal Arsenal. It is true that in the discussion which followed Col. Maitland disclaimed any originality for the Royal Arsenal, but it seems, to say the least of it, curious that he should have occupied so much space in describing a process which was perfectly familiar to everybody in the audience, had he been aware that it was in use in every civilised steel-producing country in the world. Of course this line of conduct compelled Dr. Siemens to speak in his own defence, and the stories which he told of the conduct of the Royal Arsenal authorities towards himself ought to have been sufficient to make Col. Maitland ashamed of some of his own predecessors in office, or of their immediate superiors in Pall Mall. Not only has the Siemens open hearth process of steel manufacture been appropriated without thanks or even acknowledgment, but on a former occasion they endeavoured to imitate his regenerative furnace without his cognisance, by employing a former draughtsman in his office. The furnace failed, having cost the country some thousands of pounds, and then, and not till then, was Dr. Siemens' help called in. It is really time that the Government claim to appropriate all patents without consulting or rewarding the owners should be inquired into, for the present policy cannot even be commended on the score of economy, for in the case in point the blundering of inexperienced engineers cost the country far more than the few hundred pounds of royalty which would have been due to Dr. Siemens.

We are glad to infer from this paper that there is some hope that wrought iron will shortly be entirely superseded by steel in the manufacture of ordnance. Really the caution in this matter which has been hitherto observed at Woolwich exceeds the bounds of prudence and sense. For years past the most eminent metallurgists and users of steel in every branch of manufacture have over and over again declared publicly that steel is in every respect, including ductility and toughness, vastly superior to iron, but we still find at Woolwich Arsenal that wrought iron is used for all the coils of a gun. All that Col. Maitland can bring himself to say on this point is, "but now that the pressures" (of the powder) "are longer sustained, it becomes advantageous to thicken the inner tube of steel, and it will most likely be found beneficial to support it with steel in place of wrought iron." We welcome the conclusion, though we fail altogether to appreciate the soundness of the reasoning which has led up to it; for if it is advantageous now when pressures are weak to use the stronger and tougher material, it must have been doubly so when the internal strains generated by the powder were greater than at present. The remainder of this paper calls for no special comment. It is undoubtedly interesting as an official statement, but in style it seems to us to betray the fact that the author is dealing with information which he has only recently acquired; otherwise how does he betray himself when addressing an audience composed exclusively of technical men into dwelling with minuteness on such trivial details as, for instance, the use of soap and water as a lubricant for cutting tools, in place of oil? Surely he ought to be aware that the same practice obtains in nearly every workshop in the country.

Of the remaining papers read before the Institute, one by the Assistant-Superintendent of the Enfield Small Arms Factory was a mere chronicle of the various details of the manufacture and inspection of Martini-Henry rifles and bayonets. Another, by Mr. Butter of the Royal Arsenal, was a short account of the application of steel and iron to the manufacture of gun carriages and slides. The last paper which we shall notice was by M. Ferdinand Gautier of Paris, on the Application of Solid Steel to the Manufacture of Ordnance and Small Arms. M. Gautier had already communicated two papers to the Institute on the remarkable Steel Castings of the Terre Noire Company. The peculiarity of the castings of this Company is their freedom from blow-holes, which is attributed to the rather considerable percentage of silicate of manganese used in the manufacture.

At Bofors, in Sweden, the same process is used with perfect success in the production of steel barrels for artillery.

The following analysis is given of the material produced:—

Carbon	Silicon	Manganese	Sulphur	Phosph.
0·45	0·351	0·540	Traces	0·042
0·40	0·322	0·612	0·02	0·045
0·50	0·183	0·360	0·02	0·040

The tests of this steel, both ordinary tensile tests and in guns, when fired with heavy proof charges, are stated to have given most satisfactory results.

NOTES

On Monday a preliminary meeting was held in the Mansion House in furtherance of the scheme of the International Electrical Exhibition which it is proposed to hold at the Crystal Palace on a very large scale in the winter months. There were present, among others, Mr. William Spottiswoode, Mr. John Holms, M.P. (one of the Lords of the Treasury), Mr. Mungo M'George (Chairman of the Crystal Palace Company), Capt. Douglas Galton, C.B., Dr. Gladstone, F.R.S., Col. Gouraud, Dr. J. Hopkinson, F.R.S., Mr. C. V. Walker, F.R.S., and many more. Mr. Mungo M'George, in moving the appointment of an influential honorary council to advise with the directors of the Crystal Palace in carrying out the proposed exhibition, said that no effort should be wanting on their part to make the scheme a great scientific and commercial success. The honorary council was formed of those present, and, among others, the Lord Mayor Elect, the President of the Institute of Civil Engineers, Dr. C. W. Siemens, Prof. Adams, Sir H. Cole, Prof. Fleeming Jenkin, Mr. W. Crookes, Sir E. J. Reed, M.P., Sir Edward Watkin, M.P., Sir Herbert Sandford, and many more. Major Flood Page, the manager of the Crystal Palace, read a report, which stated that communications have been opened with the leading exhibitors at the Electrical Exhibition in Paris, and with others who have made the development of electricity their special study; and, although but a very short period has elapsed since the first steps were taken, the responses have been such as to render it certain that an effective and varied display will be made at the Crystal Palace. Most of the best-known systems of electric lighting will be represented—among others, the Siemens, Brush, British Electric, Electric Light and Power Generator Company's systems, the Joel, Pilsen, Edison, Swan, Maxim, Weston, Lontin, Rapieff, and Gerard lights; and various new lamps will be exhibited for the first time in public. The storage of electricity will, it is hoped, be illustrated by Faure's and De Meritens' secondary batteries. Telephones, which are not nearly so much used in England as elsewhere, will be strongly represented; and the various applications of electricity as a motive power will be seen in Trouvé's boats and other interesting exhibits. Many eminent scientific men have expressed great interest in the undertaking, and intend to become exhibitors. Colonel Gouraud promised all the help of his fellow-countrymen towards the success of the Exhibition, which, though following that at Paris very sharply, might be more attractive to American exhibitors, for it would be one stage nearer home, and its arrangements would be conducted in a language which the exhibitors could understand. Capt. Galton expressed a hope that military and submarine electricity would be suitably and adequately represented on the occasion. Sir James Anderson also supported the proposal, which was carried unanimously. Major Flood Page then read a *résumé* of the arrangements for the exhibition, which stated that the principal objects to be admitted were comprised in the following:—Apparatus used for the production and transmission of electricity; magnets, natural and artificial; mariners' compasses; applications of electricity—*as* telegraphy and the transmission of sounds, to the production of heat, to lighting and the production of light, to the service of lighthouses and signals, to apparatus giving warning, to mines, railways, and navigation, to military art, to fine arts, to galvano-plastic, electro-chemistry, and to chemical arts, to the production and transmission of motive power, to mechanical arts and horology, to medicine and surgery, to astronomy, meteorology, geodesy, to agriculture (in its application to industries), to apparatus for registering, to domestic uses, lightning conductors. Major Page earnestly hoped that Mr. Fawcett would allow the Post Office exhibit at Paris to be shown at the Crystal Palace, and that Mr. Childers, as Secretary of State for War, would give aid to experiments as to [illegible] applied to military purposes.

At the first meeting of this session of the Birmingham Philosophical Society, the Rev. H. W. Crosskey honorary secretary, read his annual report, in which it was stated that the Council had reported that Dr. George Gore, F.R.S., had accepted the position offered him, and that the amount of 150*l.* per annum had been allotted to him in order that he might have opportunities for continuing in Birmingham his original researches. The Council had forwarded a report stating that since he had been engaged with grants from the Birmingham Endowment Fund, he had made, partly with the aid of those grants, the following researches in physics and chemistry, which had been communicated to the Royal Society, and published, or [illegible]: Thermo-electric behaviour of aqueous solutions with platinum electrodes; influence of Voltaic currents on the diffusion of liquids; experiments on electric osmose; phenomena of electric osmose; influence of Voltaic currents on diffusion of liquids and phenomena of the capillary electroscope. He hoped he might long to submit to the Philosophical Society an original paper on capillary electroscope; electric currents caused by liquid [illegible] cation. In addition to the before-mentioned researches, which as an entirely separate matter, he had been asking the assistance original research by preparing for publication a small book, "The Scientific Basis of National Progress," and it was [illegible] being printed.

A new zoological station is to be established at Banyuls-sur-Mer, on the Mediterranean, at the end of the natural breakwater tion of the mole at the beach of Fontaulé. The building will be of considerable size, have several apartments, and be well lighted. It is expected that the laboratory will be ready for work by January. M. Lacaze-Duthiers intends to illuminate the aquarium by electricity. This station will really be an annex to that at Roscoff, permitting the study of marine zoology to be carried on in winter, when it has often to be suspended on the colder coast of the Atlantic. The municipality of Banyuls is mostly very humble individuals living in an out-of-the-way place have lent cordial and substantial support to the enterprise.

The arrangements for the festival in honour of the twenty-fifth anniversary of Virchow's appointment as Professor to the University of Berlin—an anniversary which coincides with his sixtieth birthday—are now being made, we learn from the *Lancet*. An influential committee, comprising the names of Prof. Hofmann, Director of the Royal Ethnological Museum, Town-Councillor Friedel, Prof. Küster, Dr. Voss, Herr Ritter, &c., have asked permission of the Town Council to grant the use of the large hall in the Rathhaus and to defray the cost of the decorations, as on the occasion of the banquet to Dr. Schliemann. The 13th of November has been fixed for this festival. The most important part of the proceedings will be the handing over to Prof. Virchow the title-deeds of a new institution to be devoted to the prosecution of scientific researches especially relating to anthropology, of which he will have the full control. As a politician, an anthropologist, and an antiquarian, no less than as a pathologist, Prof. Virchow has claims not on Germany alone, but on the whole of civilised humanity; and we heartily join in the desire to do him honour.

The first general meeting of the London Sanitary Protection Association was held on Tuesday at the Society of Arts, Adelphi, Prof. Huxley, the president, in the chair. Mr. Holmes, the treasurer, stated that the Association had been in operation only for a few months, and for a certain portion of that time its action had been suspended by legal difficulties. The number of members enrolled up to the 15th of [illegible] was 126, the total contributions [illegible] with a loss of [illegible]

Digitized by Google

from Prof. Jenkin, for the purpose of advertising and starting the Association, was 391*l.* 11*s.*, and the total expenditure 346*l.* 3*s.* 6*d.* Prof. Huxley said that, to put it briefly, the Association was a co-operative store for the supply of good advice, and the modest success which had hitherto attended it was very likely due to the antipathy inherent in human nature to the reception of good advice. Their good advice, however, had this peculiarity—that they did not expect anybody to take it unless he liked. His interest in this Association came from the remote connection he once had with medicine and hygiene. Whatever suspicion of knowledge he ever possessed had led him to the conviction, strengthened by every day's experience of life, that when we aggregated close upon 4,000,000 of people on something less than fifty square miles, if we did not take care we should be desolated, not like old London by the plague or black death, but by those other forms of disease, as fatal in their way, which have the terrible peculiarity of being easily disseminated by the means we took to get rid of them, unless those means were perfect. Disagreeable as the old cesspool system was, it was attended with very little danger compared with that which waited upon the water sewage system if that system was imperfect, for then it was an admirably-contrived arrangement for distributing disease and death in our own houses and in the houses of people who lived adjacent. There were two ways of meeting the danger. One was by the action of Government in some shape or other; but in England no one would tolerate the intrusion of Government officials for the purpose of knocking about and looking into everything, and besides, the expense and difficulty of working such a system would put it out of the range of the practicable. The other way was to meet the danger by means of those who supplied a good report, such as that Association would do. Therefore it was for the public good that the Association should become a great one, and its work be carried out as widely as possible.

THE success which has attended Dr. Vines' English edition of Prof. Prantl's "Elementary Text-Book of Botany" has induced the publishers, Messrs. W. Swan, Sonnenschein and Co., to arrange for a companion volume on zoology, viz. an English adaptation of Prof. Claus's "Handbuch der Zoologie," which Mr. Adam Sedgwick of Trinity College, Cambridge, has undertaken to make. Hitherto this work has appeared without illustrations in Germany; but for the present edition between 500 and 600 drawings have been prepared by Prof. Claus himself. The book is announced to appear next spring. We learn also that Dr. Vines has undertaken for the same firm a "School Botany," covering the ground commonly taken up in the school course. The important treatise on the "Theory and Practice of the Microscope," by Professors Naegeli and Schwendener, which Messrs. Sonnenschein and Co. have had in the press for the past three years, has at length reached completion. It is announced for issue next month.

IT is stated that the Report of the Commission appointed in 1879 to inquire into the sanitary condition of the cemeteries in and around Paris negatives, generally, the popular belief in the noxious influences of great burial-places. The composition of the air in the cemeteries, according to M. Schutzenberger, is not distinguishable from that of arable lands.

UNDER the title of "Prehistoric Devon" (the opening address of the seventieth session of the Plymouth Institution), Mr. R. N. Worth, the president, has brought together in an interesting form many valuable data and references on the subject from all quarters.

IN No. 9 of the *Chrysanthemum*, the monthly magazine for Japan and the East, to which we have already referred, published in Yokohama (London: Trübner), there is the the first instalment of a useful vocabulary of Aino words by Mr. W. Dening.

MISS E. A. ORMEROD, authoress of the "Manual of Injurious Insects," delivered a lecture on Thursday afternoon to the students of the Royal Agricultural College, Cirencester, on the methods of investigating attacks of insects on crops, and the general treatment to be employed. The lecture was profusely illustrated by enlarged diagrams, and was enthusiastically received by the students and their friends. The lecture will be published in full.

THE death is announced, at the age of fifty-three years, of Mr. James Craig Niven, curator of the Hull Botanic Gardens.

THE Abbé Moigno's journal, *Les Mondes*, has again, we are glad to notice, passed successfully through a crisis. A fresh start has been made, the old title "Cosmos" becomes more prominent, and a bright-coloured cover has been added. Better paper, more illustrations, and re-arrangement of matter will, we trust, procure the journal increased support.

AT the meeting of the Institution of Mechanical Engineers at the Memorial Hall, Albert Square, Manchester, to-morrow, the following papers will be read and discussed:—On Bessemer steel plant, with special reference to the Erimus Works, by Mr. C. J. Copeland of Barrow-in-Furness; on compressed air upon tramways, by Mr. W. D. Scott-Moncrieff of London; on meters for registering small flows of water, by Mr. J. J. Tylor of London.

J. B. LIPPINCOTT AND CO. have in the press "The Honey-Ants of the Garden of the Gods, and the Occident Ants of the American Plains," by the Rev. Henry C. McCook, D.D.

A VIOLENT shock of earthquake, lasting three seconds, occurred at Agram at 10 p.m. on the 23rd inst.

La Nature of October 22 has a long article, with microscopical illustrations, on the drinking water of Paris.

SOME interesting facts are brought out in a paper by M. C. Nielsen of Christiania on the impression produced upon animals by the resonance of the vibration of telegraph wires. It is found that the black and green woodpeckers, for example, which hunt for insects in the bark and in the heart of decaying trees, often peck inside the circular hole made transversely through telegraph posts, generally near the top. The phenomenon is attributed to the resonance produced in the post by the vibration of the wire, which the bird mistakes as the result of the operations of worms and insects in the interior of the post. Every one knows the fondness of bears for honey. It has been noticed that in mountainous districts they seem to mistake the vibratory sound of the telegraph wires for the grateful humming of bees, and, rushing to the post, look about for the hive. Not finding it on the post, they scatter the stones at its base which help to support it, and, disappointed in their search, give the post a parting pat with their paw, thus showing their determination at least to kill any bees that might be about it. Indisputable traces of bears about prostrate posts and scattered stones prove that this really happens. With regard to wolves, again, M. Nielsen states that when a vote was asked at the time for the first great telegraph lines, a member of the Storthing said that although his district had no direct interest in the line proposed, he would give his vote in its favour, because he knew the lines would drive the wolves from the districts through which they passed. It is well known that to keep off the ravages of hungry wolves in winter the farmers in Norway set up poles connected together by a line or rope, under which the wolves would not dare to pass. "And it is a fact," M. Nielsen states, "that when, twenty or more years ago, telegraph lines were carried over the mountains and along the valleys, the wolves totally disappeared, and a specimen is now a rarity." Whether the two circumstances are causally connected, M. Nielsen does not venture to say.

WE are informed that the lists of papers, &c., appended to Mr. C. R. Markham's "Fifty Years' Work of the Geographical Society," referred to in our leading article of last week, were not compiled by Mr. Eyre.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynamolgus* ♀), from India, presented by Mr. G. R. J. Glennie; a Rhesus Monkey (*Macacus erythræus* ♀) from India, presented by Miss Richardson; a Malbrouck Monkey (*Cercopithecus cynosurus* ♂) from West Africa, presented by Mr. J. Pope; a Black-faced Kangaroo (*Macropus melanops* ♂) from Australia, presented by Miss Drax; a Black-headed Gull (*Larus ridibundus*), European, presented by Master Rew Lloyd; two Common Kestrels (*Tinnunculus alaudarius*), British, presented by Masters John and Charles Godfrey; a Snow Bunting (*Plectrophanes nivalis*), North European, presented by Mr. H. A. Macpherson; a —— Monkey (*Macacus*, sp. inc. ♂) from Hainan Island, China, deposited; a Sooty Mangabey (*Cercocebus fuliginosus* ♂) from West Africa, an Ariel Toucan (*Ramphastos ariel*) from Brazil, a Naked-footed Owlet (*Athene nudipes*), European, an Ornamental Hawk Eagle (*Spizaetus ornatus*), a Black Tortoise (*Testudo carbonaria*), an Argentine Tortoise (*Testudo argentina*) from South America, two Radiated Tortoises (*Testudo radiata*) from Madagascar, purchased; a Gaimard's Rat Kangaroo (*Hypsiprymnus gaimardi*), born in the Gardens.

OUR ASTRONOMICAL COLUMN

COMET 1881 *f* (DENNING).—From the elements of the orbit of this comet it is evident that it was a much more conspicuous object about the time of perihelion passage in the middle of September, than when it was detected by Mr. Denning on the morning of October 4, and its not having been sooner discovered can only be attributed to the general prevalence of clouded skies in September. Mr. Denning writes us that from September 2 to 29 he could not make a single observation before sunrise, owing to cloudy weather, but that on the mornings of September 29 and October 1 he missed the comet "in some unaccountable manner." The comet having escaped in September, the systematic examination of the sky, which is now pursued by him, is thus explained.

It ought now to be possible to decide by calculation from accurate positions, whether the comet be one of short period or not. The resemblance of the orbit to that of the fourth comet of 1819 has been pointed out. That comet was undoubtedly moving in an elliptical orbit of very limited dimensions; a computation founded upon a new reduction of the observations made at the Observatory of Paris, which alone are precise enough for the purpose, has led Mr. Hind to a period of revolution of 5·155 years, which is somewhat longer than that deduced by Encke in 1820 from the same observations as they were published at the time by Bouvard. At the previous aphelion passage in 1817 the comet would pass in close proximity to the planet Jupiter, and considerable perturbations may have then occurred. In the interval between the perihelion passage of the comet of 1819 and that of Mr. Denning's comet there are twelve periods of 5·151 years, and the comet would again be greatly disturbed by Jupiter near aphelion in 1853, so that it is possible to explain to a great extent the differences between the orbits of 1819 and 1881, but that the period of revolution should not have undergone material alteration at the same time, may perhaps be considered as an argument against the identity of the comets. However, as we have intimated, the question should soon be decided by direct calculation. Less than a fortnight's observations have been shown in more cases than one to be sufficient to give pretty close approximations to the periods of comets moving in small ellipses, as in the case of De Vico's comet of 1844, for which from only eight days' observations M. Faye inferred a revolution of 5·15 years, the correct one being 5·146 years, or that of Brorsen's comet at its first appearance in 1846, when from ten days' observations Mr. Hind assigned a revolution of 5·319 years, the true one being 5·569 years.

The following positions of Mr. Denning's comet are from an ephemeris calculated by Dr. Oppenheim for Berlin midnight:—

		R.A. h. m. s.	Decl.
October	28 ...	10 10 0 ...	+ 14 31·8
	30 ...	10 13 1 ...	14 32·3
November	1 ...	10 15 52 ...	14 32·7
	3 ...	10 18 35 ...	14 33·1
	5 ...	10 21 7 ...	14 33·4
	7 ...	10 23 30 ...	14 33·4
	9 ...	10 25 44 ...	14 33·4

The intensity of light on November 9 is less than the day of discovery.

HERSCHEL'S "GARNET SIDUS."—This [illegible] Cephei of our Catalogues, appears to require [illegible] vation than, to judge from published statements, it has received, and is an object well deserving the [illegible] some one of our many amateurs. No doubt [illegible] observations are attended with some difficulty from the colour of the star, but on that account the [illegible] observer may perhaps be deemed more suitable. [illegible] the new edition of his "Celestial Objects for Common scopes," assigns it a period of five or six years, obviously a mistake. It has been included amongst [illegible] variables, and its period may be usually about [illegible] of several years. Argelander, as an approximation [illegible] gives 431·8 days, from observations between 1848 and [illegible] there are very material perturbations. He considered the period of increase of brightness [illegible] in the proportion of 4 to 3. The greatest [illegible] is in R.A. 21h. 39m. 53·7s., Decl. + 58° 14′ 21″.

This star, which was not observed by Flamsteed, first of Ptolemy's *duplicatæ*, under the constellation [illegible] which he places in 13° 40′ of Pisces with 6d. south [illegible] second Radcliffe catalogue to the variable [illegible] catalogue—the first year of Antoninus, or A.D. 138—its longitude to be in 14° 16′ of Pisces, with [illegible] 64′·7, so that, as was first shown by Argelander (*Astron. Beobachtungen auf der Sternwarte zu Abo*, Erganzungsheft), the identity is beyond doubt.

GEOGRAPHICAL NOTES

THE St. Petersburg Correspondent of the *Times* writes as follows:—The question of the existence of volcanoes in Central Asia, especially on the Kuldja frontier, has always been a matter of doubt and discussion among geologists and Russian explorers. The Governor of Semiretchinsk, Gen. Kolpakofsky, had twice fitted out expeditions to settle the question—once in 1878, and again in 1879; but owing to the difficulties of access to the mountains, which the Chinese consider impassable, and to the disorders which were then taking place in Kuldja, both expeditions were unsuccessful. This year General Kolpakofsky again set himself to the task, and now reports that he has actually discovered the perpetual fires in the Tokun Shan range of mountains. He telegraphs that the most important of these is to be found twelve miles north east of the city of Kuldja, in a mountain which have been burning there from time immemorial. The volcanic, but proceed from burning coal. On the sides of the mountain there are caves emitting smoke and sulphurous gases. The *Official Messenger*, referring to this interesting subject, observes that the question as to the existence of volcanoes in Central Asia, which has so long agitated the learned world, is now irrevocably decided in the affirmative, and on the testimony of many Russian explorers. Mr. Schuyler also, in "Turkistan," mentions that there perpetual fires in the mountains referred to by Chinese historians were considered by Severtzoff, who explored the region, as being caused by the ignition of the seams of coal or the carburetted hydrogen gas in the seams. The same author further mentions that the Tosofskey, another Russian explorer, was told of a place in this crevice there had existed from ancient times those of neighbourhood from which steam constantly rose, and the inhabitants where persons afflicted with rheumatism or skin diseases were in the habit of bathing.

MR. DEGWARD, of the China Inland Mission, has lately made a lengthened journey in the Chinese provinces of Hupeh and Szechuen. he has sent home jottings that fall under the [illegible] from Wuchang, opposite Hankow, on the Yang-tsze, [illegible] five and a half months, and during which he [illegible]

Digitized by Google

province, so notorious for its turbulent braves, whose hostility to foreigners is proverbial. Mr. Dorward has however established the fact that a European, with two native assistants, can now traverse the province in safety. Near the city of Shênchi, some 450 miles from Wuchang, he had an opportunity of observing the processes used for extracting gold-dust from the sand, which consist in roughly sifting and afterwards using quicksilver.

THE Argentine Government has just despatched two officials to survey five thousand square leagues of country in the neighbourhood of the Neuquem, one of the chief tributaries of the Rio Negro. This extensive tract of country is close to the Andes, and is said to be extremely fertile. When the survey is completed the Government will dispose of the land with a view to its early colonisation.

THE Commercial Geographical Society of Bordeaux in its last *Bulletin* publishes a useful topographical note on the itinerary followed by the Upper Niger Surveying Expedition from Kita to Bamaku.

THE Department of the Interior in Canada has issued a new map of Manitoba and the North-West Territories, showing the country surveyed, &c., and in a later edition the line of the Canadian Pacific Railway will be shown.

WE hear that the Dépôt de la Guerre at Paris has just issued the first sheet of Col. Perrier's map of Tunis, drawn from his recent topographical survey of the country, which has been awaited with much impatience by French geographers.

PÈRE DUPARQUET, the well-known missionary traveller, who returned to South-West Africa early in October, has recently commenced the publication, in *Les Missions Catholiques*, of an account of a journey made by him through Ovampo Land as far as the River Cunene. He travelled in company with Mr. Erchison, one of the principal traders of Omaruru, who also had with him a son of the late Mr. C. J. Anderson. Père Duparquet's memoir is illustrated by a sketch-map of the region, on which is shown a singular connection between the River Cunene and Lake Etosha.

IN the new number (Heft 3, Band 4) of the *Deutsche geographische Blätter*, all the existing information on Wrangel Land and Herald Island has been collected, and will be of interest at present in connection with the missing *Jeannette*. Dr. Albrecht Penck of Munich contributes an interesting article on glaciation with special reference to Eschscholtz Bay in Kotzebue Sound on the north-west coast of America; and Herr G. Kreitner gives a detailed account of the Koko Nor and the surrounding region. There are besides a variety of notes on various points of geographical interest.

TO the Austrian *Monatsschrift für den Orient* for October, M. Z. Janiczek of Port Saïd contributes a letter containing a good deal of valuable information on the trade of the Red Sea. In a letter from Herr Hansel of Khartoum we find some interesting information from Dr. Emin Bey. Among other things he tells us that there are three lakes to the north of Victoria Nyanza; that Beatrice Gulf certainly does not belong to Albert Nyanza, but to a lake lying from the south; that steamers now go regularly from Dufilé to Mahagi, a station on the west coast of Lake Albert; and that the only radical cure for the Central African slave-trade is the importation of free Chinese colonists. Prof. Blumentritt contributes notes on some important vegetable products and branches of industry in the Philippine Islands.

HEFT 1, for 1880–1, of the *Mittheilungen* of the Hamburg Geographical Society contains a paper of great interest on the distribution and relative value of cowrie shells by Herr John E. Hertz. These shells are used as money mainly in the region between the Niger and the coast of Africa, though they are also in use in other parts of the world. Herr Hertz gives the exchange value of these shells in the various regions where they are used, and traces their history as a trading medium. A kindred paper, of much practical value and considerable interest, is on the barter-trade of Africa, by A. Wörmann. A long paper, with chart, on the paths of barometric minima in Europe and on the North Atlantic, and their influence on wind and weather in North Germany, by Dr. W. Köppen, is of considerable scientific interest. There is also a lecture by Dr. J. Classen on a visit to Olympia.

ACCORDING to the latest census the population of Japan on January 1, 1880, was 35,925,313. Of these 18,210,500 were males, and 17,714,813 females. When the numerous and destructive civil wars of the last twenty years are remembered, this relative proportion of the sexes will appear striking. Writers of the last century held very exaggerated notions of the population of Japanese towns, but the present census shows that some of them may properly rank among the most populous cities in the world. Tokio and its environs has a population of 957,121; Kioto, the old capital, of 822,098; and Osaka, 582,668. The smallest population of any district is that of the Bonin Islands, recently annexed to Japan, which contain only 156 inhabitants, composed of officials and descendants of Kanakas and deserters from English and American whaling-vessels.

CAPT. JOHN MACKAY, of the ss. *Southern Cross* (Auckland), sends us, along with a note, an account by himself in the *Queenslander* of his discovery and settlement of the district of Mackay in Queensland. To the now flourishing town of Mackay we referred some time ago in connection with a special number of the *Mackay Standard*. The town bids fair to become one of the most flourishing in Queensland, though its discoverer does not seem to have met with the recognition he deserves.

SOLAR PHYSICS[1]

II.

AT the conclusion of my last lecture I stated my belief that those changes which are continually going on at the surface of the sun had their origin in currents of convection, and I illustrated the processes which are there going on by what we know to be going on on the surface of our own earth. I referred, but only historically, to a theory which was thrown out many years ago as to the origin of solar heat by Sir William Thomson, according to which it depended on the impact of meteoric bodies. I did not suppose at the time that he still retained that theory, regarding it as the most probable; in fact he gave it up many years ago, and I was glad to find, from conversation with him after the lecture, he is quite of the same opinion as I am, that these disturbances—the enormous disturbances which take place at the surface of the sun, have their origin in currents of convection. I stated my belief that the spots were produced by the downward rush of, comparatively speaking, cool portions of gas which had been in the first instance ejected during these eruptions. In speaking to Mr. Lockyer afterwards I found that he had obtained independent evidence from his spectroscopic researches that these spots consisted of down-rushes of gas, and not, as some have supposed, of up-rushes. He may have mentioned it to me before; if so I must apologise for it having passed from my memory. I will not however say anything about the evidence on which he was led to that conclusion, because he is going to lecture himself, and of course he will be the proper person to explain his own discoveries.

Now with regard to these spots I have hitherto said nothing except as to their existence. The German astronomer Schwabe assiduously observed them in the beginning of 1826, and for about a quarter of a century he went on constantly observing them and making careful drawings of them. As the result of this long-continued and careful work, he was led to the conclusion that these spots as to their frequency and magnitude appear to be subject to a periodical inequality. The period appeared to be about ten years, during which, supposing you start with the maximum of spots, they dwindle away to the minimum, then after some years again rise afresh, and by the end of ten years or thereabouts you get to the maximum. M. Wolf of Berne has discussed the subject, and referred back to older observations, and was led to the conclusion that the period was longer than ten years. He makes it eleven years, or perhaps more exactly nine periods per century.

I will now come to some phenomena observed on the earth with which the solar spots would, at first sight, appear to have no possible connection. You are all, of course, familiar with the magnetism of the earth, by the aid of which our ships are navigated through the ocean. Now it has been long known that the magnetic needle is subject to disturbance; by the magnetic needle I mean the magnet suspended so as to turn freely round a vertical axis. For a long time after the discovery of magnetism that was the only kind of instrument used for the observation, and it had been observed that these disturbances were of two kinds. There was a regular diurnal movement of the needle to the west, and then to the east, of its mean position,

[1] Lecture by Prof. Stokes, Sec. R.S., in the South Kensington Museum Theatre, continued from p. 598.

Digitized by Google

and besides that there were from time to time irregular, or apparently irregular, disturbances following no observable law. It was known, too, that the diurnal fluctuation, which has now been known considerably more than a century, was greater in summer than in winter. It had been also observed that these apparently irregular fluctuations in the direction of the magnet are observed when an aurora is seen.[1] If there is an aurora there are sure to be these fluctuations, and if there are these fluctuations the probability is, if other circumstances permit, that we shall see an aurora. The connection between the two was made out about the year 1750, so that it is by no means new. Of course we cannot expect that for every magnetic disturbance we shall have a visible aurora; for in the first place the disturbance may take place in the day-time, in which case of course no aurora can be seen; then, supposing even it takes place at night, it may be that at the time the whole sky is covered with clouds, which prevent the aurora being seen; or again, it may be a bright night with the moon shining brightly, not far from the full, and then a faint aurora would not attract much notice. In fact I have often felt in doubt when I saw a luminous streak in the sky on a moonlight night whether it was an auroral streamer or merely a mare's-tail cloud illuminated by the light of the moon. After watching some time one can generally determine which it is, because if it be an auroral streamer it is pretty sure to be unsteady; but if the observer happens to have a small spectroscope in his pocket, or even a prism and a slit, the distinction can be made out at once, on account of the peculiar spectrum of auroral light.

There appears then to be evidently some intimate connection between magnetic disturbance and the aurora. The recent progress of telegraphy has caused us to be familiarly acquainted with another electrical phenomenon, or, if you like, magnetic phenomenon—that, in fact, has long been admitted—for considerably more than a century.) I allude to the earth-currents. In telegraphy we have occasion to use insulated wire, the ends of which are placed, or may be placed, in connection with the earth. Now when that is done it frequently happens that, without sending any current from the battery at all through the line, there is a more or less powerful current transmitted along the wire, which is made evident by the deflection of the galvanometer. In fact, in certain cases these currents are so strong that they interfere with the working of the lines.

At the failure of the first Atlantic cable in 1865, Sir William Thomson (whom I am happy to see before me) made some experiments with these earth-currents, as they are called, transmitted through this cable. The failure was of such a nature as would have been caused if there was a breakage in the cable something like 300 miles off, and currents were transmitted through the cable, indicating an electromotive force, as it is called, amounting to one or two Daniell's cells; on one occasion to five or six; and currents more powerful even than these are observed from time to time.

Now it is well known that at times of magnetic disturbance we have these earth-currents powerful; and as I mentioned that magnetic disturbances and auroræ come together, we have here a third phenomenon, that of earth-currents, which accompanies the two former. These three are evidently intimately connected with one another, whatever be the cause of that connection. But at present I have said nothing whatever of the relation of these three phenomena to the sun. Of course any one would say there is the remote relation, that it is to the radiation from the sun that all the great changes that take place on the surface of the earth are due: the evaporation of moisture, the heating of the air, and consequent production of winds; and in a remote sense, therefore, there would in all probability be a relation between these three phenomena and the sun. But that relation is very far from remote. I forgot at the proper time to mention one circumstance connected with these earth-currents before I came to the sun, which, if you will allow me, I will do now. I mean the magnetic disturbances.

One of the first fruits of the establishment of regular magnetic observatories was the remarkable discovery that these magnetic storms occurred simultaneously over large tracts of the earth's surface; so that even the sudden and apparently capricious variations of say the direction of the declination needle would be observed simultaneously at the same moment of absolute, not local time, at places far separated from one another, such as London and Paris, and London and Lisbon even. [illegible] of this magnetic disturbance, whatever it may be, [illegible] very widely spread. In discussing the results which [illegible] obtained at the colonial magnetic observatories, [illegible] Sabine made a remarkable discovery, namely, that [illegible] take the range of ordinary diurnal fluctuations of the [illegible] whether you take the frequency and magnitude of [illegible] to be a decennial period, or a period nearly decennial, [illegible] corresponded to the period of solar spots, corresponding [illegible] as to the duration of the period, but also as to the [illegible] maximum; so that in those years when the sun [illegible] unusual number of spots of unusual magnitude, both [illegible] diurnal variation of the magnet was greater than the [illegible] and there were more numerous and more violent [illegible] storms; on the other hand, when the sun was comparatively free from spots, the magnetic elements were, [illegible] speaking, in a tranquil state. In the older observations declination was the only one of the magnetic elements which [illegible] been observed, but all three components of the magnetic [illegible] were observed in these observatories, and accordingly [illegible] nomena could be more searchingly investigated. [illegible] search has fully confirmed this connection, so that there [illegible] no doubt now that there is some intimate connection, [illegible] be its nature, between solar spots and magnetic disturbance.

I will mention one circumstance which is a remarkable [illegible] boration of this observation. The late Mr. Carrington [illegible] years was engaged in a series of most careful and [illegible] measurements of the positions and magnitudes of [illegible] spots. The way he worked was by throwing a large [illegible] of the sun by means of an equatorially-mounted [illegible] with its eyepiece suitably focussed, on to a fixed screen [illegible] day he was engaged at this work when he saw two [illegible] spots on the screen. His first impression was that the [illegible] which was used to shut off the light of the sun, which [illegible] would have passed down outside of the object-glass of the [illegible] scope, outside the tube, had got disarranged somehow or other, [illegible] and that it was merely the sun shining through the [illegible] coming on the screen. He moved the telescope a little, [illegible] these spots moved with the image of the sun, proving that [illegible] not merely the sun shining through holes in the shading [illegible] but that they really belonged to the sun. They remained [illegible] some minutes, during which they moved over a very [illegible] portion of the sun's disk at such a rate that the actual [illegible] tion of them must have been—I forget the figures, but I [illegible] was something like 100 or 150 miles per second. Many [illegible] of them passed over a dark spot, which is confirmatory of [illegible] observation of Wilson, that the spots are at a lower level [illegible] the general surface of the sun.

Now it so happened that on examining the records of the [illegible] netic needle, which were kept automatically by a photographic [illegible] process at Kew, just at the moment when these spots were [illegible] there was an unusually great magnetic disturbance. Well [illegible] what can be the connection between these apparently [illegible] similar, apparently so disconnected phenomena, and what [illegible] cause in the first instance of the three terrestrial phenomena [illegible] first mentioned—magnetic disturbances, auroræ, and [illegible] currents?

Different theories have been started as to this connection. Some have supposed that the disturbance of the magnetic needle was an electro-magnetic effect due to the earth currents; others have supposed, on the contrary, that the earth currents were due to the electro-magnetic induction produced by a change in the magnetism of the earth. But what of the aurora? It has been recognised that the aurora is an electrical phenomenon. It has been supposed to be imitated—and there can be no reasonable doubt that the supposition is a correct one—by sending a powerful ordinary electric discharge through a highly-exhausted tube. But whence comes the electromotive force requisite to effect such a discharge? My colleagues are not in any way responsible for what I am going to advance. I am going to suggest a cause in this phenomenon which, so far as I know, has not hitherto been broached,[2] and of course you must take it for what it is worth. It has not seen the light, and therefore has not had the opportunity of being subjected to the criticism of men of science. It is open to laboratory experiments are to be any guide to us it requires to

[1] At least of the dancing kind: faint, steady auroræ do not seem to be accompanied by sensible magnetic disturbances.

[2] A number of photographic records from various magnetic observatories have recently been compared and discussed by Prof. [illegible] of Adams. This refers to the theory as a whole; the individual points of a [illegible] usually formed finales, so to speak, of one or other [illegible] taken in their entirety, may be regarded as quite distinct.

Digitized by the

inconsiderable electromotive force to send an electric discharge through even a moderate length of rarefied air, though it passes far more freely through rarefied air than through air at the ordinary pressure. I will endeavour to show you that experimentally.

[An experiment was here exhibited in which the coatings of a Leyden jar were connected with the terminals of a Holtz machine, and also, by two branches, with each other, each branch involving an interruption by air. One branch led through a universal discharger, the brass knobs of which were separated half or three-quarters of an inch, the other through a long tube filled with rarefied air—a so-called aurora tube. The second branch being at first broken, the knobs were adjusted to a distance not too great to allow the spark of the jar to pass without fail. The connection with the terminals of the aurora tube being now restored, the discharge, which was at liberty to pass by either branch, chose the aurora tube.]

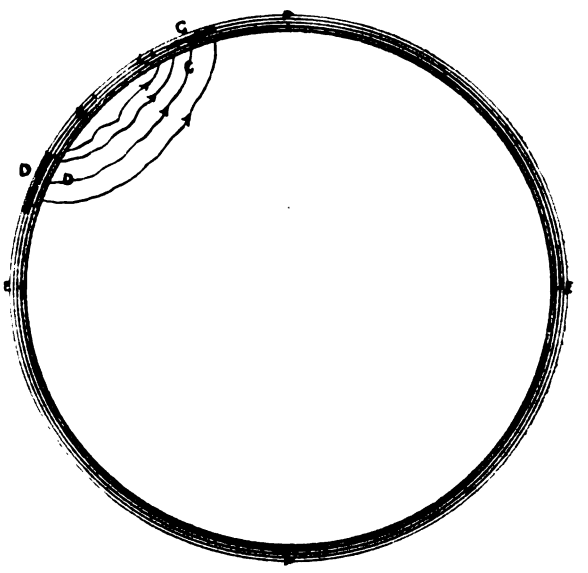
It appears then that the resistance to the passage of the electric discharge is greater across about three-quarters of an inch of air at ordinary pressure than across the whole length of the tube, which I suppose is somewhere about five feet, so that, although there is considerable resistance to the passage of the electric discharge through rarefied air, it is very much less than through air at ordinary pressure; but although it is very much less, it is very far indeed from being inconsiderable. Mr. De La Rue has a splendid battery of about 11,000 cells of chloride of silver. It required about 2000 of these to send electric discharges through tubes perhaps two or three-quarters the length of that, but not quite so broad, exhausted to such a degree as to oppose least resistance to the passage. We see then that, if one may judge by laboratory experiments, it requires a very considerable electromotive force to send an electric discharge through even a moderate distance in rarefied air.

Now attempts have been made to measure the height of the aurora, and very large figures have been brought out. It is said to be fifty or sixty, or even eighty miles high; I think some have made it even higher than that. It is a difficult matter of course to measure with much certainty, because you want a base to measure from; and the two stations must be distant a few miles, in order that you may get a sufficient angle of parallax. Then with observers situated a few miles apart it is a difficult matter, with such a variable and indefinite phenomenon as aurora, to fix on what they should observe. Possibly in the future, when such observers may be put in connection by telephone and be able to speak to one another and tell each other what sort of aurora they see, and settle by conversation at that distance what particular part they shall observe, we shall get more certain results. However, there can be no doubt that, although there may be some uncertainty as to the precise height of the aurora, it is very high indeed.

Now, even in spite of this great height, the auroral streamer subtends a very considerable angle at the eye of the observer. If this be a discharge, the length of that discharge must be very considerable, probably many miles. Where shall we get the electromotive force sufficient to send a discharge through so great an interval of air, rarefied though it be, and that not too highly? I say "and that not too highly," because experiments with exhausted tubes have shown that the resistance to the passage of the spark through the tube goes on diminishing as you make the exhaustion higher, until you reach a certain point, after which it goes on increasing again, and this exhaustion, at which the resistance to the passage of the discharge is least, is by no means very considerable as exhaustions go nowadays. Tubes have been so exhausted that rather than strike across a millimeter within the tube from terminal to terminal, the discharge would pass some inches outside in air. Well, then, it would appear from that that we do not gain so very much as regards facility of passage for an electric discharge by going up to a tremendous height in the air. Where then can we get an electromotive force sufficient to send an electric discharge through such a length? Sir William Thomson, in the case of the Atlantic cable which failed the first time, as I said before, obtained earth-currents indicating an electromotive force of a few Daniell cells; but a few Daniell cells, or a few scores of Daniell cells, or a few hundreds of Daniell cells would be quite insufficient for sending a discharge through such a space as I have spoken of, if laboratory experiments are to be any guide. There is, however, one instance of electric phenomena where we have tremendous tensions to deal with—I mean atmospheric electricity. In the case of the atmosphere we may have the electric spark striking all the distance from a cloud to the earth, perhaps half a mile or a mile. I need not say that the electric spark I refer to is a flash of lightning. Here I found some difficulty in getting the discharge to strike through air of ordinary density, across more than about three-quarters of an inch, but in lightning it strikes all that distance that I mentioned. Atmospheric electricity of tension sufficient to strike across a mile of air at ordinary density (or at least slightly reduced as you go up) might have an opportunity of striking across many miles of rarefied air, and if the experiment which I have showed you just now with that tube is to be any guide, then it would be competent to do so. In atmospheric electricity it is conceivable that we may have a sufficient tension to cause the electric discharge to strike across that great distance which the length of an auroral streamer must be.

It has long since been remarked that displays of auroræ seem in some way or other in high latitudes to take the place of thunderstorms in low latitudes. Well, then, I will endeavour to explain what I imagine takes place. I do not enter into any speculation as to the cause of atmospheric electricity. We know as a fact from its manifestation that it exists, and that is sufficient for my purpose. Suppose now that the air, especially the higher portions of the air, over a large tract of country, say to the north of us, were more or less highly electrified—positively or negatively, as the case may be—we will suppose positively—if the electric tension were sufficient, although, considering that the air is a non-conductor, we might not have a flash of lightning, which gathers into itself in one moment the electricity from an entire cloud and sends it down into the earth (we might not have tension enough to produce such a discharge, the resistance to the passage of electricity from one portion of the air to another, which at any rate would be comparatively dry compared with what we have in warm latitudes, would prevent it by itself alone), we might nevertheless have a discharge taking place in the higher regions of the atmosphere where the air is rarefied, and accordingly opposes less resistance to the discharge.

Now let me refer to this figure. This great circle, P E ρ e, I suppose to represent a section of the earth by a plane passing



through its centre. This blue [faint in cut] outside represents the atmosphere, the height, of course, being enormously exaggerated, in order to make it visible at a distance. Suppose in some way or other a portion of this upper atmosphere, as C, got considerably charged positively or negatively, say positively; it would act by induction on the earth below. The opposite electricity, negative in that case, would be accumulated underneath, as at C, and this portion of the earth would form, as it were, a portion of a Leyden jar, the lower atmosphere being the di-electric or glass of the jar, the upper atmosphere being partly, you may say, the di-electric and partly also the charged coating. It would be represented more precisely by an imaginary coating outside composed not of tinfoil, but of some badly-conducting substance. The positive electricity about C would be bound

Digitized by Google

down in part by the negative electricity about C, which it induces. In another portion of the atmosphere—it may be at some considerable distance from the former—you may have the atmosphere charged in an opposite way, and of course if this were negative there would be induced positive electricity below, or it might be that the whole of the atmosphere from C to D is charged positively, but at D the negative charge is much feebler than at C. The end-result would be the same; but for facility of explanation I will suppose that the upper portion in one place is actually charged with electricity of the opposite kind to what the charge is at the other. If the tension were sufficient, then there might be a striking across of the electricity of this name in the atmosphere from C to D, and in the earth in the reverse direction. Compared with the atmosphere, the earth would be an exceedingly good conductor, so that the electromotive force concerned in sending the currents from one part of the earth to the other would be, comparatively speaking, trifling, and therefore the electromotive force represented perhaps by a few scores of the elements of a Daniell's battery. Well, then, in atmospheric electricity we appear to have the tension requisite to send the discharge through a considerable space of rarefied air. Now if a discharge took place, and if it were night, and the sky were clear, it would, at least where sufficiently concentrated, be visible to us just in the same way as the discharge passing through the exhausted tube is visible, by the light it produces. It would produce in fact an aurora. The air is not a comparatively good conductor, like a thunder-cloud, from which a great quantity of electricity strikes in one moment, but is, after all, a bad conductor, so that the electricity can only pass in a spitting sort of way. We may conceive here that we have a sort of double current, yet not forming a complete circuit; nevertheless a discharge would go on nearly of the same nature as if the circuit were complete, and the effect of such a discharge on the magnetic needle would be nearly the same as that of a circuit which was complete. I will endeavour to produce a discharge in a circuit which is doubly incomplete.

[An experiment was here shown in which two Leyden jars were charged, one positively, and the other negatively, and were laid on the same wire resting on a table. On connecting the knobs the jars were discharged, and that almost completely, as it happened that the charges were almost exactly equal. The inner coatings here represent two portions of the upper atmosphere, the outer coatings the opposed portions of the earth's surface, and the glass of the two jars the intervening portions of the lower atmosphere.]

As I said, although the circuit is not complete, the electro-magnetic effect of the whole system would be nearly the same as if you had a complete circuit with an electric current passing through it. Now if there be only a sufficient quantity of electricity, we have here the elements necessary for producing a disturbance of the magnetic needle. Moreover, those disturbances, as the instruments show, are of a most fitful and apparently capricious character. They resemble in that the fitful character of electric discharges through air. I need hardly say that according to this theory the earth-current consists in the return currents produced by the statically-induced change on the surface of the earth, induced by the charged atmosphere above. When there is a neutralisation of the electricity from one part to another of the atmosphere above, the induced electricity in the earth is set free, and we have earth-currents to bring about the redistribution of the electricity on the surface of the earth.

It seems to me that this theory not only accounts for the connection between the phenomena, which could be otherwise accounted for, but enables us to conceive how it is that electricity strikes across such enormous distances in the upper regions of the air, and I think, further, it will account for some interesting features of the electric discharge which constitutes no doubt itself the aurora. I have here a sheet of blotting- or filtering-paper, and I will suppose this to represent an electrified tract of air lying over, it may be, an extensive tract of country, say somewhere to the north of us. Suppose that this air is charged positively, it will induce negative electricity on the earth below. This metallic coating on this sheet of glass [over which the blotting-paper was held horizontally at a little distance] may be supposed to represent the surface of the earth on which this negative electricity is induced. The two may be quietly in equilibrium. Suppose, however, that from some cause or other the tension becomes sufficient to enable the electricity from some point in this stratum of air to strike across higher up—because the streamers are found to be parallel to the direction of the dipping-needle, and parallel accordingly to the lines of magnetic force—higher up in the first instance; from thence I do not know where the discharges go, but I should suppose that in our country they generally go somewhere to the south of us. Now if a tract of air were pretty uniformly electrified, it would induce electricity of the opposite name underneath it, pretty uniformly distributed except about the edges, where the electrified air which was the inducing body would tend rather to overlap the electrified portion of the earth below, and where accordingly, if the charge were the same throughout, there would be the greatest tendency for the electricity to strike off and pass into the upper regions of the atmosphere, and thence probably to the south. Well, suppose now that a discharge begins anywhere, say somewhere along this edge of the paper, which I will suppose to be the northern edge. The paper which I hold in my hand is really touch-paper (such as boys use for amusement), and I will light the edge of it. Now this smouldering away of the touch-paper I conceive to represent the mode in which the rarefied air becomes successively discharged. Suppose that a discharge takes place somewhere about the edge of this sheet of electrified air covering a large tract of country, then if once a hole (so to speak) were formed, the tendency would be for the discharge to continue along that edge, because, as I said, as soon as the electricity at the edge was discharged the electricity of opposite name which had been induced on the surface of the earth below would be set free, the earth-current would be set up; and then again, what now is the edge of the electrified tract of air would be left exposed, no longer protected in the same manner as before by the induction of the electricity of opposite name beneath; the electricity would fly off from it in turn, and so on, so that there would be formed a sort of curtain composed of auroral rays, and gradually advancing, in our country usually in the direction from north to south; because we live in a sort of neutral region not too far south to see the aurora from time to time, and not far enough north to be exempt from thunder-storms. This auroral discharge, which takes the place of thunder-storms in lower latitudes in some way or other, usually occurs to the north of us, and accordingly the aurora is called the Northern Lights; but when there is a fine display it sometimes reaches down to us and goes south of us. So I say the discharge would usually begin from a place north of us, and would creep along the edge of the electrified stratum of air, forming a sort of luminous curtain, and passing from north to south, just as the smouldering edge of the touch-paper passes along the paper gradually. When we are just under the edge at which the discharge takes place we have, as I conceive, an auroral arch passing, it may be, through the zenith, generally stretching also east and west, and generally moving with a slow motion from north to south.

Now supposing that that is the explanation of the three phenomena—magnetic disturbances, earth-currents, and aurora—can we in any way connect their occurrence with changes going on at the surface of the sun? I think we can. We know that a tube containing rarefied air, supposing the density of the air in it is given, opposes less resistance to the electric discharge through it when it is warm than when it is cold. The conducting power of a wire for electricity decreases if you heat the wire, but it is the reverse with air. The passage of electricity through rarefied gases is very different in its nature from the passage of electricity through a wire or through an electrolyte. Mr. De La Rue has shown in the course the researches made by means of his splendid battery, that in these highly exhausted tubes the electric discharge, be it ever so steady to all appearance, obeys laws connecting it rather with a series of disruptive discharges, with a rapid succession of sparks, than with a discharge passing through a wire. Now connected with that difference, or at least accompanying it, there is that opposite action of heat which, as I say, in the case of gases renders the passage of electricity more easy instead of less easy. We may imagine that if from any cause the sun gives out greater radiation than usual, the upper regions of the atmosphere may thereby become heated to a certain extent[1] and oppose less resistance to the passage of the electric

[1] The rays of the visible spectrum, and even the invisible rays for some considerable distance beyond the extreme violet, pass freely through our air, which could not therefore be sensibly heated by them. But there is reason to think that the atmosphere, or some of its constituents, are more or less opaque to rays of very high refrangibility; and it is just for copious emission of these that sources of radiation of an excessively high temperature are so remarkable. The substance, which is opaque to the rays of excessive refrangibility, and consequently enables them to heat other parts of the atmosphere, is probably not nitrogen or oxygen, but some gaseous gases present in very small quantity.

Digitized by Google

discharge through it than they did before. In this way we may conceive that in a great outbreak like that observed by Mr. Carrington, where the hot interior of the sun is turned up, as it were, and radiates towards the earth, the facility for the passage of the electric discharge is increased, and it may be very rapidly increased. So that according to this theory the foundation of these three phenomena lies in atmospheric electricity, which forms as it were the magazine, and the solar radiation, as it were, supplies the match, and allows it to be discharged. Of course, over and above that, when solar radiation is active, all the phenomena which depend on solar radiation may be expected to be active too; and therefore beyond its influence in firing the match, to speak metaphorically, this solar radiation, when more active than usual, and lasting, will also produce a more rapid development of all those processes at the surface of the earth which depend on solar radiation, among others, no doubt, the generation of atmospheric electricity, although we are not at present able to explain with certainty the manner in which it is produced. So that in two ways, by applying the match to the train already laid and by gradually manufacturing the powder, the increased solar radiation may cause an increase in those electric discharges and earth-currents as the result of the redistribution of the induced electricity at the surface of the earth, and thereby a disturbance of the magnetic elements. I do not know of any other theory than that of atmospheric electricity which furnishes anything like sufficient electromotive force to account for these auroral discharges, if they are really electric discharges analogous to those which take place in exhausted tubes. As I said, it has been supposed by some that the magnetic disturbances are due to earth-currents; according to the theory which I have advanced, they are due rather to a vast assemblage of currents, partly atmospheric and partly terrestrial. An objection has sometimes been taken to the supposition that the magnetic disturbances are due to earth-currents arising from the consideration of the electro-magnetic effect which the earth-current actually observed would have upon the needle. But this, I think, is obviated when you remember that an earth-current actually observed is merely what results from the examination of a very small portion of this vast electric system, stretching it may be over hundreds of miles of country. At Greenwich, for instance, there are now wires by which earth-currents are regularly observed. The coincidence between photographic traces left by the earth-currents and those left by the magnetic storms is most remarkable. Every peak of the one, you may say, answers to a peak of the other. It has been noticed, however, that there appears to be a slight difference in the time of the occurrence. It would appear as if the disturbances preceded the earth-currents. Well, that may very well be, because, according to the theory which I have advanced, the effect on the magnet is the resultant effect of a vast series of currents, partly terrestrial and partly atmospheric, stretching over a very large region of country, whereas the earth-currents observed are merely obtained by tapping the earth at a couple of places at no great distance, so that the two do not by any means necessarily correspond exactly.

I forgot to mention at the proper time a diagram which Capt. Abney has kindly prepared for me. This is a copy of the diagram made by Mr. Ellis of the Royal Observatory, giving the result of his discussion of the Greenwich observations on two out of the three magnetic elements, namely, the declination and horizontal force, as compared with sun-spot frequency. [Mr. Ellis's diagram in Part ii. of the *Philosophical Transactions* for 1880 was then referred to.]

You see that an examination of the phenomena going on at the solar surface itself leads us to the conclusion that there are vast currents up and down, by means of which the comparatively speaking cool upper portions are continually replaced by hotter matter from beneath. Mr. Lockyer, in the lectures he is about to give, I have no doubt will have a great deal of very interesting evidence derived from spectroscopic study of the phenomena to lay before you, bearing out that same conclusion. We have seen that the supposition that there is extra radiation when the interior portions of the sun are ejected and come to the surface, falls in very well with the known relationship between the occurrence of sun-spots and the three terrestrial phenomena I have mentioned—magnetic disturbances, aurorae, and earth-currents. I say between the sun-spots, although it is not, strictly speaking, the sun-spots themselves, but the tremendous disturbances which are their precursors, and of which they form the most easily-observed manifestation.

Now if there is reason to believe that, when the sun is in a state of activity in this manner, there is increased radiation from it, it may well be that the meteorology of the earth is affected by the changes which take place at the surface of the sun; but the meteorology of the earth forms an exceedingly complicated problem. We have, so to speak, to deal here with a very complicated integral of a differential equation. I am speaking somewhat metaphorically, but my words will be understood by the mathematicians who happen to be present. We cannot very directly connect that integral with the disturbing forces. One thing, however, we may say: supposing that there is a system of any kind subject to periodic disturbing forces—and we have seen reason to believe that these great eruptions which take place on the surface of the sun are, perhaps somewhat roughly, periodic—if, I say, we have a periodic system of disturbing forces, then the system which is acted upon by these forces will show a periodic disturbance which may be more or less concealed by apparently capricious disturbances, but which yet may be expected to come out in the long run; and it has been supposed by those who have studied meteorological phenomena that there are indications of a decennial, or nearly decennial period in some of the meteorological elements, for instance, the mean temperature of the air and the fall of rain. Again, in some observatories thermometers have been sunk to a considerable depth in the earth, and observations of such thermometers were carried out for a great number of years by the Astronomer Royal of Scotland, Prof. Piazzi Smyth, and they are regularly carried out now at Greenwich. Connected with the annual variation of temperature between summer and winter there are, so to speak, waves of heat and cold slowly propagated down from the surface of the earth to the interior, rapidly decreasing in amplitude as they descend, and by going a suitably moderate depth you get these fluctuations, indicating the annual fluctuation of the atmospheric temperature, and free in a great measure from the fluctuations which take place at much shorter periods. When you go a little way down the results given by these thermometers seem to indicate something of a decennial or nearly decennial period. Conflicting statements, however, have been made by different observers as to the time of maximum of the meteorological elements which were supposed to have such a period, and some have argued from the results that when the sun was in a highly spotted condition we had a higher temperature than usual, and some the reverse. Now this is an important matter to attend to. Suppose we had such a system acted on by periodic disturbing forces; it will show at least in the mean a corresponding periodic fluctuation, corresponding however only as regards the length of the period. The epoch of maximum of the element observed, whatever it may be, has no necessary relation to the epoch of maximum of the disturbing forces, excepting that they are separated by a constant interval, and the epoch of maximum of the element observed may be different at one locality from what it is at another. So that it is only the period and not the epoch of maximum which you can expect to arrive at possibly by an observation of such elements as I have spoken of. It is very difficult indeed to say, even if a ten-yearly period be observed, what ought to be the year of greatest solar radiation if we have given the observed results.

Is there any way in which we may hope to attack that problem? I think there is. It is by no means hopeless to attempt to measure by a direct process the solar radiation. Instruments have been devised for the purpose, called actinometers. One was devised by the late Sir John Herschel, and goes by his name, and it is a very beautiful instrument; but unfortunately it is excessively fragile, and if the instrument has got rough travel or rough work at all to go through, it is pretty sure to be broken. Other instruments have been devised for the purpose, and among them I may mention one by Prof. Balfour Stewart. He has lately devised a new actinometer, and one of his construction has recently been sent out to India, and is at present under trial. In these cases heat is observed by a thermometer. Another has been devised by Prof. Roscoe, depending on the chemical action of radiation. I think none of these have yet had a thoroughly complete trial, because in such a climate as ours a fair trial can hardly be made, since there are so many disturbing elements in the lower atmosphere. An exceedingly slight cirrus-haze makes an enormous difference in the amount of heat radiated from the sun as received by us without being deflected from its course. If there be the slightest haze a good deal of the heat rays are deflected from their course, perhaps not much deflected, so that if we take in the direction of the sun itself and the neighbouring

Digitized by Google

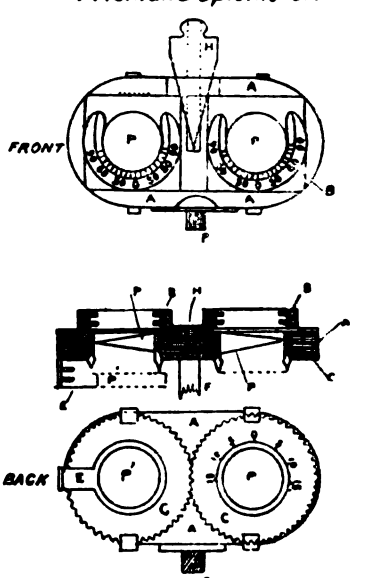
directions from the sun for some considerable distance all round it, the totality of radiation from that portion of the heavens may not be so much inferior to what it is when there is none of that slight cirrus haze there. But still we have haze enough in the lower regions, and besides that we have water in an invisible state of vapour, and Dr. Tyndall has shown that that absorbs with great avidity a portion of the heat rays. Those, however, are mainly rays of very low refrangibility. Still the absorption of these may very sensibly affect the totality of radiation received from the sun. How then shall we, if possible, get rid of these sources of disturbance? The best plan seems to be to take observations at a considerable altitude, where if possible you may get many thousand feet above the level of the sea and get rid of the lower, dustier, hazier portion of the atmosphere, and get rid also of by far the greater portion of the aqueous vapour, which by itself alone would absorb a portion of the heat. That is what the Committee on Solar Physics have attempted to do. We contemplate having actinometric observations made in the north of India. Of course, if observations are to be continued, it is not sufficient to go to some high mountain. You must go to some habitable place where the observer can live and be in some sort of comfort. Now in the Himalayas you may get up to many thousand feet and yet be still within reach of human habitations; or what is better still, if you cross the range and go over into Thibet, you have there a high table-land many thousand feet above the level of the sea, with a sky usually cloudless, and where observations of this kind may, it is hoped, be made with success for a considerable period together, and the result may, we hope, in time throw light on the question whether or no there is in reality a change in the amount of radiation received from the sun, and whether the amount of that change is sufficient to make any material difference in the meteorological conditions of our globe.

I have spoken of meteorological elements in which various observers suspected that they saw some indications at least of a decennial, or nearly decennial, period. Speculations have been made as to whether there is not a decennial period, or something of the kind, traceable even in the occurrence of Indian famines. If so, there may be some very close relationship between the solar spots and these famines. At first sight one would be disposed to say, "What possible connection can sun-spots and famines have with one another? You might as well speak of the connection between comets and wars!" But when we go deeper below the surface, and study carefully the phenomena presented to our view, we see that a possible connection between such apparently remote things as sun-spots and famines may not be chimerical; and there is no saying what practical application may in the end result from a study of solar phenomena undertaken in the first instance for a purely scientific object.

A PRISMATIC OPTOMETER[1]

IT is well known that in the normal eye, with its accommodation relaxed, parallel rays of light, that is, those from distant objects, are brought to a focus on the retina. Rays from near objects are divergent, and if they enter such an eye they are not brought to a focus on the retina, but would be at some point behind it. In order that they may be so brought to a focus and form a distinct image on the retina, an effort of accommodation is necessary. This is performed by a small muscle called the ciliary muscle, inside the eyeball, the ultimate effect of whose contraction is an alteration in the shape and perhaps the condition of the lens, which causes the rays to be more strongly refracted, and brings them to a focus on the retina. The effect is in fact the same as if a convex lens were added to the optical system of the eye. As age advances, the muscle and lens become stiffer, and work with difficulty. They are relieved of part of their work by putting a convex glass in front of the eye. Hypermetropia is a condition in which the axis of the eyeball is too short, compared with the refracting power of the lens. In it an effort of accommodation is necessary to see even distant objects clearly, and a still stronger effort to see near objects. A person suffering from it requires convex glasses. When both eyes are used together, the optic axes of both are directed to the object, so that in looking at a distant object they are directed parallel, and in looking at a near one they converge. These movements are effected by the external muscles of the eyeball, which are supplied by branches of the same nerve as the ciliary muscle. As a fact these movements of the ciliary muscle and of the external muscles of the eyeball are associated, or habitually performed in conjunction; that is, the brain has become accustomed to send an impulse to the one set of muscles proportionate to that sent by the other. Any disturbance of this association can only be accomplished by a distinct effort which, if severe or long continued, is apt to be painful. Suppose a man has become presbyopic, *i.e.* his accommodation has gradually become stiff, and its range reduced. In order to accommodate for rays from an object at the ordinary reading distance of ten or twelve inches, he has now to exert an effort equal perhaps to what he would have employed when young on one four inches off, but the change has been gradual, and the convergence of the eyes for twelve inches has become associated with this amount of effort. If he now use convex glasses of suitable power, the want of refracting power is supplied, the effort of accommodation is reduced to its natural amount, but the amount of convergence which has become associated with this small effort is now insufficient, and the eyes, instead of converging to twelve inches, converge on a point several feet distant, so that double vision would be produced, unless by a distinct effort the eyes were converged more, and

Eye End of Dr. T. Anderson's Prismatic Optometer.



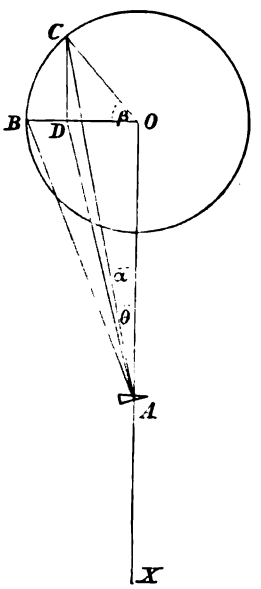
A, main frame carried by F, graduated rod; C, rotating frame carrying P P, prisms; E, frame carrying P', third prism; H, wedge to separate the frames for lenses.

this effort is often painful, and is expressed by the term that the spectacles "draw" the eyes. After a time new associations are formed, and the spectacles can be used comfortably; but this does not happen in all cases, and for these it is necessary to grind the lenses on glasses of prismatic section. The action of the prism is so to bend the pencils of rays coming to the eyes that they appear to diverge from a point corresponding to the new focal distance of the eyes provided with the spectacles. Sometimes the amount of prismatic effect required is calculated, but the calculation, being based on general considerations, does not always suit individual persons; at other times prismatic glasses from a trial case, are combined with the calculated spherical, or spherical and cylindrical glasses, until one is found with which vision is comfortable. In many cases it is not necessary to use glasses specially ground on prisms, but sufficient to move the centre of the glasses nearer together. The glass being thicker in the centre, looking through the part near the edge produces an amount of prismatic effect which is often sufficient. If concave glasses are used, as in cases of short sight, then they must be further apart than the distance of the eyes, in order to produce this effect. The object of the instrument exhibited is to find experimentally the amount of prismatic power, and the distance of the centre of the lenses which is

[1] "On a Prismatic Optometer," by Tempest Anderson, M.D., B.Sc., read at the York meeting of the British Association.

Digitized by Google

required in any individual case. Two circular frames each 2½ inches in diameter, and with teeth cut in their edges, are mounted, so that the teeth gear into each other, and they can rotate freely, but in opposite directions. In the centre of each frame is mounted a prism of 18°; one of the frames is graduated, and when the graduation is at 0° the axes of the prisms are parallel, so that parallel pencils of rays falling on both are deviated both in the same direction, and still parallel. Thus when the pair of prisms are arranged horizontally in front of a pair of eyes, an object looked at appears displaced up or down, but there is no lateral deviation on either. If the frames be rotated 90° in one direction, the prisms both have their bases inwards, or, if in the other direction, both outwards, so that two pencils of rays are deviated to the full power of the prisms. In the intermediate positions part of the prismatic effect is resolved in a direction at right angles to the line joining the centres of the frames, and can be neglected as only producing parallel displacement of the image, and part is resolved in the direction of this line so as to produce apparent separation or approximation of the images. This amount is read off from the graduation, which is constructed on the following principle:—Suppose a ray of light X A O perpendicular to the plane of the paper meets the paper at O. Suppose a prism be introduced at A



having an angle of deflection θ, the ray of light now falls on the paper at B. If the prism be rotated through angle β, the ray now falls on the paper at C. Join O B, O C, and resolve O C into vertical and horizontal co-ordinates C D, O D. C D being neglected as described, we wi h to find O D the horizontal component of the deflection.

$$\text{Since } OB = OC$$

$$\therefore \frac{OD}{OB} = \frac{OD}{OC}$$

$$\therefore \frac{\frac{OD}{OA}}{\frac{OB}{OA}} = \frac{OD}{OC}$$

$$\frac{\tan \alpha}{\tan \theta} = \cos \beta$$

$$\text{Log cos } \beta = \text{Log tan } \alpha - \log \tan \theta.$$

Two other frames are placed in front of the prisms. They contain grooves to hold lenses or combinations of lenses, and are graduated so that cylindrical lenses can be set at any desired angle. The frames can be separated or brought nearer with greater accuracy by a wedge, and the distance of the centres of the glasses is marked on the bearing. The whole is carried at the end of a graduated bar which carries a sliding support for an object. This bar is graduated in inches for use in calculation and also in focal lengths of a set of dioptric lenses. A third prism is attached, so that it can be placed between one of the frames and the object. When it is in position, the rays going through it to the eye appear to come from an object higher than when it is absent. Double vision is produced, and the eyes left free to find their most comfortable position free from any effort to make the two images coalesce. To use the instrument, the spherical and cylindrical elements of the spectacle required are first found either by some of the ordinary methods or by the ophthalmometer described in the Annual Volume for 1880, and the required lenses from the trial case put in the appropriate frames. The third prism is interposed, and an object, such as a vertical line, looked at at reading distance. If the images seen by the two eyes are exactly one above the other, the prismatic adjustment is presumably correct, the third prism is removed, and trial is made whether reading can be carried on for some time without fatigue. If the images are slightly displaced externally, trial is made whether shifting the centres of the lenses nearer or further off suffices to bring them into position. If so, the distance is noted and sent as a direction to the optician. If the displacement be more than can be corrected by this means, the prisms are rotated till the desired effect is produced, and the amount of prismatic deviation to be given to the proposed spectacles read off. The third prism is removed, and reading practised as above.

SCIENCE AND INDUSTRY[1]

CONSIDERING the high position in literature and science of my predecessors in this chair, I feel that I have been bold indeed in accepting the distinguished office of President of the Midland Institute during the current year. I shall not attempt to rival my predecessors in those literary or philosophic flights which befitted their powers, but shall confine myself to certain suggestive remarks flowing from personal experience of men and matter, which may prove of some interest to an audience consisting in the main of persons who, like myself, are intent upon combining science with practical aims, but who, unlike myself, have the best part of their career still before them.

In venturing to express my views regarding the great question of the day, that of Technical Education, I shall run considerable risk of disappointing some of its most ardent advocates, who may have looked upon me, a foreigner by birth, as a staunch supporter, if not as the living embodiment, of that particular form of education that the Polytechnicum of Germany and other Continental countries imparts to the aspiring engineer and manufacturer, but which, in my opinion, leaves much to be desired, and is certainly inapplicable to the condition of things which we find in this country.

The subject of education, and of science education in particular, is one the practical and national importance of which it would be difficult to over-estimate. It is well known that the Continental nations have in some respects stolen a march upon us in providing for the education of the young engineer, the architect, the manufacturer, and the craftsman. Colleges of high and low degree abound where both science and practical processes are taught, whereas the teaching of the latter has been looked on hitherto amongst us as professional or trade knowledge to be acquired during lengthy periods of pupillage or apprenticeship.

The more ardent advocates of the Continental method of technical education go so far as to think that the irksome system of apprenticeship should give way entirely to technical teaching within the college walls, whereby it is assumed much time could be saved and a better knowledge be imparted to the aspiring engineer or manufacturer. Having had some experience of young men brought up at these technical schools, I am bound to say that I have not been favourably impressed with the results produced by that system. The practical knowledge acquired at those establishments is wanting in what may be called the commercial element, that is of due regard to cost of production, of which the teacher himself must be comparatively ignorant, as otherwise we should find him employed at the factory or engineering office, instead of in the schoolroom.

The young polytechnic student is apt to look on the machine or process which he has studied, not as one of many solutions of a practical problem influenced by ever-varying external circumstances, but as something representing an absolute condition of things almost as completely proved and established as a first

[1] Abstract of Address at the opening of the Birmingham Midland Institute, by Dr. C. W. Siemens, F.R.S., president of the Institute.

Digitized by Google

principle in nature, or a proposition of Euclid; he is very proud of this positive knowledge, and impatient of any suggestion aiming at the accomplishment of the same object by means not sanctioned by his authoritative text-book. He is apt to be a dogmatist, a splendid man for coming out first-class in a competitive examination, and likely enough to make a good official in a Government administration, but most unlikely to venture of himself on such new embodiments of first principles of nature as are essential to the accomplishment of improved results, and as have animated our Watts, our Cromptons, our Corts, and our Bessemers in enriching the world with new processes.

On the Continent, where the Governments themselves are largely engaged in trade and enterprise, where railways, mines, and factories are State establishments, it was necessary to create a large staff of men educated to the point of being able to assume at once a position of some authority in the ranks of rigid organisation, and such men are provided by the polytechnic schools. Our Indian Government being similarly situated, had to resort to similar means, and to establish Cooper's Hill Engineering College.

In this country, where happily the great commercial interests, with one exception, are still in private hands, educational establishments on the Continental model would be, I consider, inappropriate. The object a young man has in view is not the attainment of a snug position in a Government establishment, but to be fitted by his education for the great battle of life, in which he will be judged, not by the answers he can give to certain set questions in his competitive examination, but rather by the faculty he may have acquired of realising useful results under even adverse circumstances and conditions.

The time was, not long ago, when the opinion prevailed in this country that useful knowledge could only be attained in the workshop; that a lad, after having mastered the three R's at a primary school, had to be bound to a manufacturer or craftsman for a period of seven years, where his time was occupied in routine work or in mechanical repetitions of one and the same operation, causing him to give up thinking altogether, and to become what was dignified by the appellation of practical man—a man of notions, with a supreme contempt of theory or science. The reign of this practical man *par excellence* is happily drawing to a close; for those who wish to treasure up his memory, I would recommend a lucid description of him by my friend Sir Frederick Bramwell in his presidential address to the Mechanical Section of the British Association in 1872 (which may be found in the *Transactions* of that year). Since then Sir Frederick Bramwell has done much to hasten the burial of the character he describes, in making himself the principal promoter of that splendid endowment, the London City Guilds Institute, which, under wise direction, cannot fail to exercise a very important influence on the educational development of the country.

Having now spoken, somewhat disparagingly, I fear, of both the old English system and of the more recent Continental system of technical education, I shall be asked, no doubt, what in my opinion should be the plan adopted in preparing the mechanical engineer, the manufacturer, and the artisan of the future for their respective careers. The answer to such a question is one involved in much difficulty, scarcely admitting of universal solution. There are, however, certain principles of general application which, I submit, should never be lost sight of. Moral education being provided for, the main object in teaching the young should be to strengthen the power of memory, and after that the reasoning faculty. The first is most appropriately accomplished by the conventional three R's, and by the teaching of geography, history, and languages, both ancient and modern; and the second by mathematics, logic, and the natural sciences. Sir John Lubbock, in addressing you some years ago from this chair, forcibly called attention to the necessity of combining both literary and scientific education in our grammar schools, suggesting that at least ten hours a week should be given up to the teaching of science.

Such a system of education has since been established at Eton, where (as reported in NATURE, vol. xxiv. p. 287) all pupils attend science classes, and are said to be very fond of what they are pleased to call the "stinks" (in allusion to the chemical laboratory); whereas at other grammar schools a "modern department" has been added to the establishment, where science is taught to those only who elect not to go in for a classical career, whilst the classical scholars remain untaught in science as before. I am of opinion that the Eton system is the better of the two, for I cannot regard an education to be complete [illegible] combine literary with scientific training; the [illegible] polish and the other the fibre and practical [illegible] understanding. A Birmingham manufacturer [illegible] despises polish as make his goods tempting to [illegible] he would hardly like to offer them unpolished [illegible] and polish without that solid fibre in the interior [illegible] to fit them for practical usage; such intellectual [illegible] case be likened to the knowledge of useful subjects [illegible] modern languages and natural sciences, without which [illegible] polish must be devoid of the power to produce [illegible] after all is the standard to be aimed at.

The man of classics, the Bishops, the Legislators [illegible] of the future, educated at Eton, will be more [illegible] standing upon an educational foundation consisting [illegible] in its composition, whereas the man of practical pursuits [illegible] all the better for his early literary culture.

But it may be urged that the time available for [illegible] short to admit of both, and that one or other must be [illegible] chosen. I should venture to doubt the sufficiency of [illegible] tion, being of opinion that the study of the one fitted [illegible] qualifies the mind the better for the other, in the same [illegible] after life recreative exercise of mind and body is required [illegible] order to relieve the drudgery of daily duty.

The usefulness of science teaching depends [illegible] great extent upon the teacher, and upon the system [illegible] Science taught as it were by rote is of comparatively [illegible] in after life; to be beneficial it should be practical, [illegible] the mind vividly with the simplicity and the beauty [illegible] of nature, and for this purpose each statement of a [illegible] be followed up by ocular demonstration, may by action [illegible] tion on the part of the student to the experiment, [illegible] purpose no school ought to be without its chemical, [illegible] and its mechanical laboratories, where students [illegible] themselves chemical reactions, verify physical laws, [illegible] the mechanical properties of materials used in construction [illegible] do these laboratories necessarily involve a large expenditure [illegible] apparatus, the most instructive apparatus being that [illegible] built up in the simplest possible manner by means [illegible] cords, wires, and glass tubes, and, if possible, by the [illegible] requisition the constructive ingenuity of the student himself.

Only after the student has attained a thorough knowledge [illegible] first principles will it be desirable to introduce him to [illegible] instruments such as telescopes, polarisscopes, electrometers, [illegible] delicate weighing-machines wherewith to attain numerical [illegible] and to commence original research. For this reason [illegible] plete laboratories are of great importance at the universities [illegible] superior colleges, where exact science and independent [illegible] take the place of mere fuition of first principles.

After first principles have been taught at school, the [illegible] on the one hand, and the workshop, aided by study on the [illegible] hand, are requisite to impart that special knowledge [illegible] for the profession or business to be followed. In this respect the German University—that glorious institution [illegible] the development of independent thought—the advantage [illegible] much more commendable for imitation than the technical [illegible] and it is a significant fact that while the technical schools [illegible] Germany continue to increase both as regards number and high state of efficiency, the purely technical colleges, without exception, have during the last ten years been [illegible] receding; whereas the provincial "Gewerbe Schule" has [illegible] the progressive Minister, Von Falk, been modified so [illegible] approximate its curriculum to that of the "Gymnasium" [illegible] grammar-school.

In some technical schools mechanical workshops are provided [illegible] in which students may work at the lathe, the vice, and [illegible] planing-machine, and where they are allowed to construct [illegible] steam-engines or other pieces of machinery. I doubt very much [illegible] whether these toy steam-engines are such as would ever [illegible] mechanical engineer in real practice, and think that [illegible] money of the institution and the time of the student would be much better employed if, instead of imitating practical engineering, he were made to experiment with testing-machines [illegible] to obtain a thorough insight into the mechanical properties of materials, their absolute strength, their elastic limits, and the effects produced upon them by the processes of annealing, hammering, and welding. University College, London, has taken the lead in this respect under the able direction of Prof. [illegible], and example will, I hope, be followed by other colleges.

As regards middle class education, [illegible]

that, at the age of sixteen, the lad is expected to enter upon practical life, and it has been held that under these circumstances at any rate it is best to confine the teaching to as many subjects only as can be followed up to a point of efficiency and have reference to future application. It is thus that the distinction between the German Gymnasium or Grammar School and the Real Schule or Technical School has arisen, a distinction which, though sanctioned to some extent in this country also by the institution of the "modern side," I should much like to see abolished.

But I shall be told that it is impossible to teach everything properly within the time, and shall be reminded of the proverb that says, "A little knowledge is a dangerous thing." I, for one, do not believe in this proverb, which I consider erroneous, and mischievous in its application. Referring to myself as an example, I am sorry to state that I had not the advantage of being taught Greek at school beyond the mere letters of the alphabet—my early education having indeed been irregular and cut short much too soon—which surely is the minimum of knowledge that could possibly be possessed of that language. Yet even this amount of knowledge of Greek has stood me in good stead, because it has enabled me at any rate to use those letters in mathematical formulæ, and on a push to puzzle out some of those Greek names which are given to scientific instruments. In this case, at least, exceedingly little knowledge has proved no danger, but a considerable advantage to me, and it would not be difficult to multiply examples to the same effect. A little knowledge of a modern language will be best appreciated by an English person who, speaking no language but his own, has occasion to go abroad. Arriving at his destination he finds that he is unable to make the railway porter understand what conveyance he intends to take, and where he intends to go; his perplexity will be still greater when, on entering a restaurant, say at Paris, he is presented with a bill of fare extending over several pages, from which to select his dinner. In despair he points at random to some of the enumeration of dishes, and finds to his discomfiture that the one is presented to him in the form of a *pâté* of snails, another as a preparation of legs of frogs, and the third as water ice with which to appease an appetite quite equal to roast beef, potatoes, and cheese.

In physical science a little knowledge may be a matter of the greatest importance to an artisan when he is called upon to set a machine to work, and is stopped by some such accidental cause as the accumulation of air below a valve, or unequal expansion due to a local source of heat. The knowledge of a few fundamental laws of physical science will at once enable him to divine the cause of difficulty, which has only to be recognised in order to be removed. I should therefore be disposed to reverse the proverb, and to say that "a little knowledge is an excellent thing," only it must be understood that this little is fundamental knowledge; that it is not the knowledge of the conceited pretender who has committed to memory a few scraps of information of a particular subject; who quotes a Greek author without having learned as much of the language as I have; who speaks of planetary perturbations without having a knowledge of the fundamental law of gravitation; or who pretends to know all about steam-engines without having the least knowledge of the laws of heat, of elasticity, or of dynamics involved in their action.

On the whole I am inclined to agree with Lord Brougham, who, himself a great lawyer and a lover of science, gave origin to the pithy expression, "Try to know something about everything, and everything about something." It would be hard, indeed, to realise the latter portion of his saying, but it would be difficult to know even a good deal about something without knowing at least something about a great many other things.

The question of education becomes even more difficult when we approach the condition of the artisan who needs to send his boy into the mine or factory at the tender age of twelve years. I am of opinion that fourteen years should be the minimum age at which lads should be admitted into works, in order that they may have had not less than four years of judicious training at elementary or Board schools, where in addition to the purely elementary subjects, at least so much of general history, easy mathematics, and natural science should be inculcated as to implant, if possible, the desire to acquire more of those subjects in after life. School education, whether followed up to one point or another, can after all do no more than lay a foundation and implant, if possible, a desire in the mind of the student, to follow up the subjects taught in maturer years with the experience of life present to give a practical direction to his studies.

In order to aid him in these endeavours, such bodies as the Midland Institute must prove to be of great service, with its science classes and lectures open to all who thirst after knowledge and who want to understand more particularly the scientific principles involved in their occupations. Technical education such as this is indeed indispensable if this country is to maintain the supremacy won for it by men of exceptional genius, enterprise, and perseverance, but which without it can hardly be expected to withstand in the long run the competition of foreign nations, with cheaper labour and a higher standard of general education in their favour. The English system of technical education has this advantage over the system established elsewhere, that it is not governmental but essentially spontaneous and self-supporting, and will therefore shape itself into the mould best suited to the free and vigorous development of trade itself.

The system of pupillage or apprenticeship will still be necessary, but instead of involving the sacrifice of seven of the most important years of a young man's life, half that time, or say three years, will be found amply sufficient to give to the lad imbued with first principles the practical knowledge necessary for his trade. The employer would be amply compensated for the shorter time of gratuitous service by a corresponding improvement in its quality. He should be expected to see to it that during the term of his authority the pupil attended Saturday and evening classes, where, in addition to general subjects, the principles underlying the operations of his business of spinning, dyeing, paper-making, or metal-working are taught by competent persons.

It is important that the teacher himself should not be a mere specialist, but a man capable of generalising and of calling to his aid other branches of science and general knowledge, that he should be, in short, a well-educated person. It is difficult, I believe, as yet to find a sufficient number of teachers equal to such a standard, and in order to supply this deficiency normal schools will have to be established upon a much larger scale than has hitherto been the case. It is satisfactory to learn that South Kensington is coming to the rescue in converting its science teaching into a normal school for the education of science teachers; only it is to be hoped that literary subjects will be added to their curriculum.

The importance of a higher education of the working classes will be appreciated by all who have watched the rapid strides with which one branch of industry after another undergoes fundamental change, by which the mere craft-skill acquired yesterday becomes obsolete to-day, when a new process, involving entirely new modes of operation, takes the place of a previous one. Nor is there any promise of stability in the process of to-day, which may be again superseded to-morrow by something more nearly approaching ultimate perfection.

To those who still have some confidence in the stability of things as they exist in arts and manufactures, I would strongly recommend a trip to Paris, where they will still be in time to visit the International Exhibition of Electricity. That form of energy known as the electric current was nothing more than the philosopher's delight forty years ago. Its first practical application may be traced to this good town of Birmingham, where Mr. George Elkington, utilising the discoveries of Davy, Faraday, and Jacobi, had established a practical process of electroplating in 1842.

It affords me great satisfaction to be able to state that I had something to do with that first practical application of electricity; for in March of the following year, 1843, I presented myself before Mr. Elkington with an improvement on his processes, which he adopted, and in so doing gave me my first start in practical life. Considering the moral lesson involved, it may interest you, perhaps, if I divert for a few minutes from my subject in order to relate a personal incident connected with this my first appearance amongst you.

When the electrotype process first became known, it excited a very general interest, and although I was only a young student of Göttingen under twenty years of age, who had just entered upon his practical career with a mechanical engineer, I joined my brother Werner Siemens, then a young lieutenant of artillery in the Prussian service, in his endeavours to accomplish electro-gilding, the first impulse in this direction having been given by Prof. C. Himly, then of Göttingen. After attaining some promising results, a spirit of enterprise came over me so strong that I tore myself away from the narrow circumstances surrounding me, and landed at the East End of London with only

Digitized by Google

a few pounds in my pocket and without friends, but with an ardent confidence of ultimate success within my breast.

I expected to find some office in which inventions were examined into, and rewarded if found meritorious, but no one could direct me to such a place. In walking along Finsbury Pavement I saw written up in large letters "So and so" (I forget the name), "Undertaker," and the thought struck me that this must be the place I was in quest of; at any rate, I thought that a person advertising himself as an "undertaker" would not refuse to look into my invention with a view of obtaining for me the sought-for recognition or reward. On entering the place I soon convinced myself, however, that I came decidedly too soon for the kind of enterprise here contemplated, and finding myself confronted with the proprietor of the establishment, I covered my retreat by what he must have thought a very lame excuse. By dint of perseverance I found my way to the patent office of Messrs. Poole and Carpmael, who received me kindly and provided me with a letter of introduction to Mr. Elkington. Armed with this letter, I proceeded to Birmingham to plead my cause before your townsman.

In thinking back to that time, I wonder at the patience with which Mr. Elkington listened to what I had to say, being very young, and scarcely able to find English words to convey my meaning. After showing me what he was doing already in the way of electro-plating, Mr. Elkington sent me back to London in order to read some patents of his own, asking me to return if, after perusal, I still thought I could teach him anything. To my great disappointment I found that the chemical solutions I had been using were actually mentioned in one of his patents, although in a manner that would hardly have sufficed to enable a third person to obtain practical results.

On my return to Birmingham I frankly stated what I had found, and with this frankness I evidently gained the favour of another townsman of yours, Mr. Josiah Mason, who had just joined Mr. Elkington in business, and whose name as Sir Josiah Mason will ever be remembered for his munificent endowment of education.

It was agreed that I should not be judged by the novelty of any invention, but by the results which I promised, namely, of being able to deposit with a smooth surface 3 dwt. of silver upon a dish-cover, the crystalline structure of the deposit having theretofore been a source of difficulty. In this I succeeded, and I was able to return to my native country and my mechanical engineering a comparative Croesus.

But I was not to remain there, for in the following year I again landed in the Thames with another invention, worked out also with my brother, the Chronometric Governor, which, though less successful, commercially speaking, than the first, obtained for me the advantage of bringing me into contact with the engineering world, and of fixing me permanently in this country. This invention was in course of time applied by Sir George Airy, the then Astronomer-Royal, for regulating the motion of his great transit and touch recording instrument at the Royal Observatory, where it still continues to be employed.

Another early subject of mine, the anastatic printing process, found favour with Faraday, "the great and the good," who made it the subject of a Friday evening lecture at the Royal Institution. These two circumstances combined obtained for me an entry into scientific circles, and helped to sustain me in difficulty until, by dint of a certain determination to win, I was able to advance step by step up to this place of honour situated within a gunshot of the scene of my earliest success in life, but separated from it by the time of a generation. But notwithstanding the lapse of time, my heart still beats quick each time I come back to the scene of this, the determining incident of my life.

At the time I am speaking of, the electric telegraph was occupying the minds of the philosophers of different countries, but it was not until the year 1846 that the first practical line of telegraph was established between Paddington and Slough, where it soon gained notoriety in preventing the escape from justice of a great criminal. It is unnecessary for me to insist upon the enormous results that have been achieved by this great modern innovation, which goes even beyond the poetic vision of Shakespeare himself, who in the extravagance of his "Midsummer Night's Dream" makes Puck "encircle the earth in forty minutes," a rate of communication which would nowadays hardly satisfy the City merchants, who expect Calcutta and New York to respond to their calls much more promptly than that.

The telegraph has found its simplest but most remarkable development in the telephone, which, although shadowed forth by Reis in 1862, was only reduced to anything [illegible] shape by Graham Bell in 1876, and subsequently Edison, Hughes, and others.

This latter invention appeared at first particularly of practical results. The currents set up through of a metallic diaphragm facing the poles of a so feeble, and the rate of succession of current produce sound (represented by 440 vibrations produce the note fundamental *la*) was so very mu thing met with in telegraphy, that it was difficult to such a succession of distinct currents with the in strength and quality necessary to reproduce spe transmitted through a line wire many miles in len reproduce mechanically the same sounds at the Yet the telephone has become a practical reality, a powers are illustrated in a very remarkable manne Exhibition.

There, in a certain room, you may listen of an minute to the performance going on at the Great C the next minute to an air sung at the Opéra Comiq the next minute to the well-known voices of the pr of the Théâtre Français. The novelty of this partic ment consists in having each receiving telephon separately to a transmitting telephone, fixed in fron lights towards the two sides of the stage, whereby effect is produced that may almost be called stereo actually hear when the actor turns his or her head fr to the other, and are able to separate most distinctly voices, as well as the orchestral instruments whe music is being produced. Nor are the sounds in any w or disagreeable, or too low to be enjoyable, but lou producing an agreeable impression even on the music person with his ears to the two receiving telephone himself in a mysterious dreamland of sound. But instruments only half an inch from the ear, and all ha no sweet sounds of music are heard, but in their speaking voice of the person anxious to take your pl auditory. I leave to your imagination to picture the fo applications which this new power of man in directing of nature may ultimately lead to.

The most striking feature upon entering the Paris in the evening is the blaze of electric light that makes t of that large building even brighter than by daylight; effect of this illumination marred by the flickering, fa colour changing of the earlier attempts in this direct character of the lights comprises a range from the cent 10,000 candle-power, to the incandescent lamp of co candles, equalling the light only of an ordinary gas-bu the grouping and shading of some of these lights are s produce effects extremely agreeable to the eye. Wh venture to say, after this display, and after the practical tions that have been made of the electric light in the London, at several of our docks and harbours, at work and theatres, that it is not a practical illuminant destined as great a change as gas-lighting did before it, thirty ye when it was inaugurated at the Soho Works not many mo from this hall?

But although I predict a great future for electric light a the most brilliant, the cheapest, and the least objectiona a sanitary point of view of all illuminants, I do not agr those who consider that the days of gas must therefore be

In addressing the British Association of Gas Manag this town a few months ago, I called attention to certain by which gas of much higher illuminating power mi obtained from the ordinary retorts, if only, at the same the gas companies or corporations could be induc supply at a reduced rate heating gas, of which w much stand in need; and how, by certain improve in the burners themselves, the illuminating power given quantity of gas might be still further augmented, companies have for many years enjoyed the sweets of monopoly position, which position is generally speaking productive of desire for change. The electric light has nished for them the incentive to advance, and the effect of incentive has told already, I am glad to observe, in a striking manner upon the street illumination of this immed neighbourhood.

The time is not far distant, I believe, when [illegible] almost entirely take the place of solid fuel for heating obtaining motive power, and for the domestic grate; and

Digitized by Google

companies and corporations rightly understand their mission, they will take timely steps to supply, separately, heating gas at a greatly reduced cost, the demand for which would soon be tenfold the gas consumption of the present day. The economy and the comfort which would accrue to the inhabitants of large towns by such a change would be great indeed, and it would, amongst other things, effect a radical cure of that great bugbear of our winter existence, a smoky atmosphere.

The third great practical illustration furnished by the Paris Exhibition has reference to the transmission of power from one place to another by means of the electric conductor. When, only five years ago, in addressing the Iron and Steel Institute, I ventured upon the assertion that the time was not distant when the great natural sources of power, such as waterfalls, would be transferred to considerable distances by means of stout electric conductors, to be there utilised for providing towns with light and motive power, I elicited an incredulous smile even from some of those most conversant with the laws of electricity. Electricity had been looked upon by them as a swift agent to flash our thoughts from country to country, but the means of producing that form of energy by the expenditure of power on the dynamo-electric machine, although known, was not yet properly appreciated. Such can hardly now be considered the case. I could point to at least three instances in this country where power is practically transmitted to a distance by means of electricity, to be utilised for pumping water, for lighting, and for working machinery, and the Paris Exhibition furnishes additional illustration of the facility with which that transmission may be effected.

The electric railway leading from the Place de la Concorde into the Exhibition, and only half a kilometre in length, does its work regularly and well, running a trip every five minutes, and conveying generally as many passengers as can be packed both inside and outside of a tram-car of ordinary dimensions. This system of propulsion will soon be in operation on a new line of railway six miles long, with which I am connected, in the north of Ireland, to be extended, if successful, to a further equal distance. This will give us twelve miles of electric railway worked without expenditure of fuel, for the motive power will be obtained from a neighbouring waterfall, which at present runs to waste. Mr. W. A. Traill, the Resident Engineer of the line, has already commenced operations, and I hope that by next spring, visitors to the sister island may reach one of its most interesting sights, the Giant's Causeway, propelled by invisible but yet potential agency.

The experience gained by my brother in the working of the first electric railway, two miles in length, established by him at Lichtenfelde, near Berlin, leaves no reasonable doubt regarding the economy and certainty of this mode of propulsion, although it is not anticipated that it will supersede locomotive power upon our main trunk railways. It will have plenty of scope in relieving the toiling horses on our tramways, in use on elevated railways in populous districts, and in such cases as the Metropolitan Railway, where the emission of the products of combustion causes not only the propulsion but the suffocation of passengers.

Another application of electricity, also at any rate indicated at the Paris Exhibition, is that to agriculture and horticulture, upon which I have been practically engaged during the last two winters on my farm near Tunbridge Wells. This is neither the time nor place for me to enlarge upon this application, which should be mentioned, however, because I believe that it will ultimately exercise a considerable influence upon an important interest, besides providing a means of adding to the pleasures of country pursuits. Electroculture by itself would be expensive, but not so if combined, as it is at Sherwood, with the utilisation of electric energy for accomplishing other objects—such as chaff- and root-cutting at one place, wood-cutting at another, and pumping of water at a third, while the waste heat of the steam at the generating station is utilised to heat the water circulating through the greenhouses, &c. In this way labour and expense are saved in many ways, and the men employed on the farm find no difficulty in working the electrical horses, no longer experimentally, but as a regularly established thing.

A somewhat special application of electricity, also shown at the Paris Exhibition, is its employment as a heating agent. For temperatures not exceeding that of a welding furnace, solid or gaseous fuel produces the desired effect at a cheaper rate than it is likely to be accomplished by electricity. When electricity is used, heat energy has in the first place to be transferred from the burning fuel to the boiler of the steam-engine. The mechanical energy of the engine works the dynamo-electric machine, whence electric energy is transmitted through the conductor to the point where it is to be utilised as heat. At each intermediate stage a loss will have to be incurred, and it is therefore absolutely certain that the amount of heat finally produced in the electric arc must fall very much short of that generated by the fuel under the boiler. But the electric arc has this advantage over other sources of heat, that no waste heat need pass away from it in the shape of heated products of combustion. This loss of heat in the furnace by combustion increases with the temperature at which the work has to be accomplished, and reaches its maximum in a furnace for melting steel or platinum. Beyond this the point is soon reached where combustion ceases entirely, where, to use the scientific phrase, the point of dissociation of carbonic acid is reached; and it is for purposes where such degrees of heat are required that the electric arc can be advantageously employed, and will enable us to accomplish chemical effects which have hitherto been beyond the reach of science.

My chief object in dwelling, perhaps unduly, upon these practical questions is to present to your minds in a concrete form the hopelessness of looking upon any of the practical processes of the present day as permanent, to be acquired in youth and to be the staple occupation of a lifetime.

The respectable millwright of former years had already to enlarge his scope of knowledge and become a steam-engine builder; having made himself master of the construction of simple forms of high-pressure engines, he has had to go to school again, to study the laws of condensation and of the expansive action of steam, in order to produce an engine using only a fractional amount of the fuel which his customers were willing to expend in former years for a given effect; he now has to study the laws of electricity and understand the construction of dynamo-electric machines, in order to be able to transmit and distribute his steam power more readily than could be accomplished by means of wheels and belts. But even his condensing steam-engine with variable expansion, of which he is so justly proud to-day, will no longer be acceptable to his client to-morrow, when it will be made clear to him, by the light of thermo-dynamics, that even the best of steam-engines utilises barely a seventh part of the heat-energy residing in fuel, and that the attainment of perhaps three-fourths of that ultimate limit will be required of him.

Analogous changes threaten to invade almost every existing branch of industry, and it is necessary for every one of you to be prepared for such changes.

The practical man of former days will have to yield his place to the unbiased worker who with open mind is prepared for every forward step as it arises. For this purpose it is necessary that he should possess, beyond the mere practical knowledge of his trade, a clear appreciation of the principles of action underlying each operation, and such general acquaintance with the laws of chemistry and physical science as will make it easy for him to adapt himself to the new order of things.

In order to be so prepared, it is by no means necessary that you should have had the advantage of an elaborate school education. No man or woman should consider him or herself out of school until approaching the final reckoning, and it is through advantages such as are offered by the Midland Institute, that the means are afforded you of continuing the educational process near your homes, and without much expense or difficulty of any kind.

Let no one of you suppose that his early training or natural ability is unequal to the task of making a career in life. Goethe, that man of wonderful insight into the working of the human mind, says:—

> "Was man sich in der Jugend wünscht,
> Hat man im Alter in Fülle."

Or, translated,

> "What you desire in youth,
> Mature age will give you in abundance."

At first sight this expression seems to involve almost an absurdity, and it is necessary to interpret the "desire" of youth to mean not simply a vague sentiment or wish to be looked up to in after life, or to drive about in easy carriages, but a determination to leave no stone unturned, and let no opportunity go past that may advance you towards the well-defined object of your ambition. With a firm resolution almost every difficulty in your way will recede before you; disappointments you will

Digitized by Google

have, and they are most desirable, because they are the real teachers in practical life, only you must not allow yourself to be discouraged, but rather to be strengthened by them, in your determination to succeed.

A fond mother has sometimes come to me with a doleful story that her son, "an excellent young man," had tried several things in life and had always failed, through some untoward circumstance, but that she felt sure he would succeed if I would only give him a trial in my own particular pursuits. On some occasions I have perhaps yielded to such representations, but found that the "excellent young man," though commencing with a certain vigour, soon tired of the new occupation when he approached its difficulties. He would not realise the fact that the secret of success lies not in the avoidance of, but in the victory over difficulties, that each disappointment teaches an important lesson, and that by taking these lessons to heart without swerving from his purpose he would soon find himself possessed of a power exceeding his most sanguine expectations.

Success in life depends in fact much more upon dili gence and steadiness of purpose than upon the more brilliant qualities possessed by an individual; but in order to give force and direction to the sterling qualities within him, it is most important that means should be brought within his reach of enriching his stock of useful information. The Birmingham and Midland Institute, counting its 3688 students of various degrees and of both sexes, has accomplished this important object in a manner never before dreamt of; but not content with this splendid result, the Council has made provision for a further extension of its beneficial action though the erection of this magnificent leisure hall, which it is my proud privilege to inaugurate this evening, for the use of our members.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—One interesting outcome of recent changes is the promulgation by the Governing Body of Caius College of the following scheme, to take the place of the regulations providing for the annual delivery of the Thruston speech on the progress of medicine from the time of Dr. Caius, by a medical graduate, who received the sum of 18*l.*:—The money—about 54*l.*—shall be given triennially to that member of the College who has published in the course of the preceding three years the best original investigation in physiology (including physiological chemistry), pathology, or practical medicine; the person to whom the prize is awarded being required to give an account of his investigation in the form of a lecture in the College. If within the specified period no investigation of sufficient merit shall have been made, the money shall be carried forward to augment future prizes; the first prize will be awarded in 1884.

SOCIETIES AND ACADEMIES

LONDON

Entomological Society, October 5.—H. T. Stainton, F.R.S., president, in the chair.—Exhibitions: Mr. R. McLachlan, a specimen of *Gastrophysa raphani*, Fabr., bred from a parthenogenetic ovum.—Mr. T. Wood, an abnormal specimen of *Nathalis Iqnitatus*, Fabr.—Mr. R. Meldola, on behalf of Mr. W. J. Argent, some interesting varieties of British *Lepidoptera*.—Mr. H. B. Pim, a specimen of *Harpalus discoidus*, Fabr.—Mr. E. A. Fitch, *Lasius mixtus*, Nyl., an ant new to Britain.—Mr. A. S. Olliff, a specimen of *Papilio Ajax*, Koll., with abnormal neuration.—Communications: the Secretary read a letter respecting the ravages of *Lagaphus cocophagus*, Newp., destructive to cocoa-nut trees in Fiji; and some further communications from the Colonial Office relative to locusts in Cyprus, &c.—Papers read: Mr. D. Sharp, Descriptions of some new *Coleoptera* from the Hawaiian Islands.—Mr. C. O. Waterhouse, on some new South American *Coleoptera* of the family *Rutelidæ*.—Prof. Westwood, description of the immature state of a Ceylonese insect apparently belonging to an undescribed genus.—Mr. P. Cameron, notes on *Hymenoptera*, with descriptions of new species.

PARIS

Academy of Sciences, October 10.—M. Wurtz in the chair.—The following papers were read:—On the first volume of the "Nouvelles Annales de l'Observatoire de Bruxelles," by M. Faye. It contains a new uranometry, and a repertory of constants of astronomy.—M. Hourgean has represented the Milky Way on a large scale by means of curves of equal luminous intensity. He distinguishes thirty-three luminous masses, carefully determining their position.—Our solar system is almost exactly in the plane of the great ecliptic circle, nearly fe[illegible], and is probably near its centre.—The "Annuaire des Constantes" comprises seventy-six determinations of parallax, extending over twenty-one centuries.—Daubrée presented a large specimen of a bolide which fell in precision of astronomical measurements is well known.—C[illegible] got before met with in a metallic meteorite.—Daubrée pre-[illegible] from Cohahuila, Mexico. It contains chromite.—Smith also found in it another chromiferous mineral, *Bolidite*.—On the employment of tar as a preservative against phylloxera, by M. Avignon. A mixture is made of tar and sand, and triturated to render it homogeneous. Water is added; the mixture is put in a hole round the vine, and covered with earth. It effectually repels the insects.—A letter of M. Govi relating to a *Brachinus* by Fontana on the unpublished will of Nicolò Tartaglia, in which the fact that the true surname of this celebrated man was Fontana. He was called Tartaglia (the stammerer), and which appears as his name, even in 1512.—Comet di-covered by Mr. Denning on 1881; observation at Marseilles Observatory, by M. C[illegible] the part of M. Arnaud, a sample of a new alkaloid from (of Santander, Columbia) was presented: M. Arnaud *chaunamine*. It differs from cinchonine by an excess of hydrogen, and presents the composition of hydrocinchonine, which it is probably isomeric.—On the sounds produced phonic circuit during thunderstorms, by M. de Lalagade. effects similar to those got by M. Thury, which he in 1878. To amplify the sounds he afterwards added microphones to the plate of the receiving telephone. sounds can thus be heard i m. or more from the second in a quiet room.—Galvanometer with angular deflections tional to the intensities, by M. Gaiffe. The moving the instrument pre-ented (a horizontal galvanometer elliptic form. The deflections are regular under 35°, about 35°, representing 35 milliwebers, on arches and then diminish slowly, allowing of division of the units to the fiftieth milliweber. With a different multiplier frame the deflections may be rendered proportional to about the seventy-fifth degree.—On the innervation M. Yung. *Inter alia*, the heart is chiefly rhythmical from the po-terior or the brauchial ganglions, which give an accelerative *rôle*. Rise of temperature accelerates the movements up to 40° C. *Curare*, in strong doses, animal's movements very slow. *Strychnine*, whatever only causes temporary convulsions, never tetanus; in direct contact with the heart it lessens the number of beats and stoppage in fifteen to thirty minutes. *Nicotine* accelerates heart-beats, enlarges the heart, and in strong doses [illegible]. *Veratrine* acts similarly, &c.

LIGHTNING CONDUCTORS.

Experience, accumulated since the time of Benjamin Franklin, proves conclusively that a Conductor made of Copper of adequate size is the best of all appliances for the protection of every description of building from the destructive effects of lightning.

NEWALL & Co.'S
PATENT
COPPER LIGHTNING CONDUCTOR,

As applied to all kinds of Buildings and Shipping in all parts of the world with unvarying success; is the most Trustworthy, most Effective, and also the Cheapest Conductor ever offered to the Public.

It is simple in its application, no Insulators being required, and it costs only ONE SHILLING per Foot for the standard size which ensures safety in any storm.

THE MICROSCOPE

AND ITS

REVELATIONS.

By WILLIAM B. CARPENTER, C.B., M.D., LL.D., F.R.S., F.G.S., F.L.S., Corresponding Member of the Institute of France, and of the American Philosophical Society.

From the Preface.

THE Author has endeavoured by a careful and thorough revision of the entire Treatise to render it as serviceable as possible to those for whom it is specially intended. Besides introducing a large amount of new matter into the first four chapters he has entirely re-written Chap. V., so as to embody in it an account of those methods of Hardening, Staining, Imbedding, and Section-cutting, which have completely revolutionised many departments of Microscopic investigation. In the sections relating to the Protophytic forms of vegetable life much new matter has been introduced in regard to the *Schizomycetes* or *Bacterium*-group, the *Myxomycetes*, and others of those curious organisms which occupy the border-ground between Vegetable and Animal life. So again in the section on the Protozoic forms of Animal life, large additions have been made under the heads *Monerozoa*, *Rhizopoda*, *Infusoria* (especially the *flagellate* and *suctorial*), and *Radiolaria*; and the section on *Sponges* has been entirely re-written. Some important additions have also been made in regard to the applications of the Microscope to Geological inquiry. In many other instances references have been made to the best sources of information upon recent discoveries of interest, which a due regard to the necessary limits of his book made it requisite for the Author to dismiss with a mere mention.

No fewer than fifty new Wood-engravings have been added, besides the reproduction of Prof. Cohn's beautiful Plate of *Volvox*, which now forms the Frontispiece.

London: J. & A. CHURCHILL.

No. LXXXIV., October. Price 7s. 6d.

THE QUARTERLY JOURNAL

OF

MICROSCOPICAL SCIENCE.

Edited by

E. RAY LANKESTER, M.A., F.R.S., F.L.S., Fellow of Exeter College, Oxford, and Professor of Zoology and Comparative Anatomy in University College, London;

With the co-operation of

F. M. BALFOUR, LL.D., F.R.S., F.L.S., Fellow and Lecturer of Trinity College, Cambridge;

W. T. THISELTON DYER, M.A., F.R.S., F.L.S., Assistant-Director of the Royal Gardens, Kew; and

E. KLEIN, M.D., F.R.S., Lecturer on Histology in St. Bartholomew's Hospital Medical School, London.

MEMOIRS:—

The Organ of Jacobson in the Rabbit. By E. Klein, M.D., F.R.S., Lecturer on Histology and Embryology in the Medical School of St. Bartholomew's Hospital. (With two Plates.)

On the Further Development of *Welwitschia mirabilis*. By F. O. Bower, M.A., Camb., Assistant to the Professor of Botany in University College, London. (With two Plates.)

On the Structure and Significance of some Aberrant Forms of Lamellibranchiate Gills. By K. Mitsukuri, Ph.B., of Tokio, Japan, late Fellow of the Johns Hopkins University, Baltimore. (With Plate.)

Limulus an Arachnid. By E. Ray Lankester, M.A., F.R.S., Jodrell Professor of Zoology in University College, London—*Continued.*

DANGERS to HEALTH: a Pictorial Guide

to Domestic Sanitary Defects. By T. PRIDGIN TEALE, F.R.C.S., Surgeon to the General Infirmary at Leeds.

"Mr. Pridgin Teale has just issued a new and greatly enlarged edition of his invaluable book, depicting the dangers to health in our own homes. Our readers will be aware that the book originated in a lecture delivered by Mr. Teale some years ago to the members of the Leeds Philosophical Society. It has since had a most remarkable and gratifying success, and has been accepted, not merely in England, but throughout the civilised world, as an authoritative exposition of the evils to be avoided in the construction of houses. The additional plates introduced in the new edition deal with the evils which were left unnoticed in the former editions."—*Leeds Mercury.*

London: J. & A. CHURCHILL. Leeds: C. GOODALL.

Messrs. MACMILLAN & CO.'S NEW BOOKS.

PROFESSOR HUXLEY'S NEW VOLUME.

SCIENCE AND CULTURE, AND OTHER ESSAYS. By Professor HUXLEY, F.R.S. Demy 8vo. [*Immediately.*

Contents:—Science and Culture; Universities Actual and Ideal; Technical Education; Elementary Instruction in Physiology; Joseph Priestley; On the Method of Zadig; On the Border Territory between the Animal and the Vegetable Kingdoms; On Certain Errors respecting the Structure of the Heart attributed to Aristotle; On the Hypothesis that Animals are Automatic, and its History; On Sensation and the Unity of Structure of the Sensiferous Organs; Evolution in Biology; The Coming of Age of "The Origin of Species"; The Connexion of the Biological Sciences with Medicine.

MR. E. A. FREEMAN'S NEW BOOK.

SUBJECT AND NEIGHBOUR LANDS OF VENICE. By E. A. FREEMAN, D.C.L., LL.D. Being a Companion Volume to "Historical and Architectural Sketches." With Illustrations. Crown 8vo. 10*s.* 6*d.*

MR. F. T. PALGRAVE'S NEW VOLUME OF POEMS.

THE VISIONS OF ENGLAND. By FRANCIS T. PALGRAVE. Being a Series of Lyrical Poems upon Leading Events and Persons in English History. With a Preface and Notes. Crown 8vo.

MR. ALFRED AUSTIN'S NEW POEM.

SAVONAROLA. A Tragedy by ALFRED AUSTIN. Crown 8vo. 7*s.* 6*d.*

MR. WILLIAM BLACK'S NEW NOVEL. *Now ready at all the Libraries.* 3 *vols. crown* 8*vo.* 31*s.* 6*d.*

THE BEAUTIFUL WRETCH: THE FOUR MACNICOLS: THE PUPIL OF AURELIUS. By WILLIAM BLACK. Author of "Madcap Violet," "The Strange Adventures of a Phaeton," "A Princess of Thule," "White Wings," &c.

"One of the prettiest and most genial stories that Mr. Black has ever written. . . . Altogether, these three volumes are worthy of their author, and will be found agreeable companions."—*Morning Post.*

NEW NOVEL.

SYNNÖVÉ SOLBAKKEN. Translated from the Norwegian of Björnstjerne Björnson by JULIE SUTTER. Crown 8vo. 6*s.*

ENGLISH MEN OF LETTERS. Edited by JOHN MORLEY. NEW VOLUME.

DE QUINCEY. By Professor MASSON. Crown 8vo. 2*s.* 6*d.*

INTERNATIONAL TRADE, AND THE RELATION BETWEEN EXPORTS AND IMPORTS. By Sir JOHN B. PHEAR. Crown 8vo. 2*s.* 6*d.*

PRACTICAL POLITICS. Published under the auspices of the National Federation. Demy 8vo. 6*s.*

Contents:—The Tenant Farmer; Land Law and Landlords, by JAMES HOWARD, M.P. Foreign Policy, by RIGHT HON. M. E. GRANT DUFF. Freedom of Land, by G. SHAW LEFEVRE, M.P. British Colonial Policy, by SIR DAVID WEDDERBURN, M.P.

RELIGION AND CHEMISTRY. A Re-statement of an Old Argument. By J. P. COOKE, Erving Professor of Chemistry and Mineralogy in Harvard University. A New and Revised Edition. Crown 8vo. 7*s.* 6*d.*

LECTURES AND ESSAYS. By GOLDWIN SMITH, M.A. Demy 8vo. 10*s.* 6*d.*

LAY SERMONS. By Professor JOHN STUART BLACKIE. Crown 8vo. 6*s.*

THE SHAKESPEARE PHRASE BOOK. By JOHN BARTLETT, Author of "Familiar Quotations," &c. Crown 8vo. 12*s.* 6*d.*

*** This book is intended to be an index of the phraseology of Shakespeare; a concordance of phrases rather than of words. Its plan is to take every sentence from his dramatic works which contains an important thought, with so much of the context as preserves the sense, and to put each sentence under its principal words, arranged in alphabetical order.

MACMILLAN'S POPULAR SIX-SHILLING NOVELS. NEW VOLUMES.

THE HONOURABLE MISS FERRARD. By the Author of "Hogan, M.P." New and Cheaper Edition. Crown 8vo. 6*s.*

HOGAN, M.P. New and Cheaper Edition. Crown 8vo. 6*s.*

ANTHROPOLOGY.

AN INTRODUCTION TO THE STUDY OF MAN AND CIVILISATION.

By Edward B. Tylor, D.C.L., F.R.S.

WITH NUMEROUS ILLUSTRATIONS.

"If all manuals were like this, a generation over-educated for its intellect would have no reason to complain. . . . His volume seems to us to serve a double purpose. It is a most attractive and entertaining introduction to the science of anthropology. . . . Mr. Tylor has acquired the art of teaching. . . . His writing is clear and luminous, and his arrangement masterly. . . . Mr. Tylor writes with as much caution as learning."—*Saturday Review.*

"It is an endeavour to put before the lay reader in a clear, condensed, and interesting form the main settled results of modern investigations into the science of man. . . . Mr. Tylor has been eminently successful in writing a very comprehensive and extremely readable book. . . . Mr. Tylor's admirable little book certainly deserves the success with which it will doubtless meet."—*Pall Mall Gazette.*

"To take in hand a chaos and reduce it to any ordinary plan; to examine the vast complex of human life in all ages and all stages, and to show how it may be treated under half a dozen main heads,—this is indeed a difficult task, yet it is one which Mr. Tylor has performed within very modest limits and with distinguished success. . . . It is neither dull nor abstract. On the contrary, every page is rich in concrete illustration and abundant colouring. Children could read the greater part of it and find it amusing, while men will find it suggestive in ideas and admirable in general arrangement. Indeed, it may be said that, slight as this little book is, Mr. Tylor has never shown his store of facts to better advantage. It is more complete and more systematic than his earlier and larger works, and it gives the results of his latest thinking in their fullest and most mature form. . . . In short it is one of the best of the useful class of scientific works which aim at giving to the non-technical but cultivated public the best results of historical investigations as they appear to a leader of thought in the special science itself. . . . The illustrations deserve the highest praise for their fidelity and the admirable way in which they bring out the minor characteristics of race, presenting a marked contrast in this respect to most ordinary attempts at representing anthropological types. . . . On the whole Mr. Tylor's treatment of all the facts is as masterly and unexceptionable as it is simple and interesting. . . . On the whole the students who read Mr. Tylor's book may congratulate themselves upon having obtained so easy, pleasant, and workmanlike an introduction to a fascinating and delightful science."—*Athenæum.*

MACMILLAN & CO., LONDON, W.C.

NOW READY, 4 VOLS. CROWN 8vo. EACH 7s. 6d.

THE ENGLISH POETS.

Selections, with Critical Introductions by Various Writers, and a General Introduction by MATTHEW ARNOLD

EDITED BY THOMAS HUMPHRY WARD, M.A.,

Late Fellow of Brasenose College, Oxford.

Vol. I. CHAUCER to DONNE.
Vol. II. BEN JONSON to DRYDEN.
Vol. III. ADDISON to BLAKE.
Vol. IV. WORDSWORTH to SYDNEY DOBELL

The following Writers have contributed to the Work:—

The DEAN of WESTMINSTER—The DEAN of ST. PAUL'S—Lord HOUGHTON—Sir HENRY TAYLOR—MATTHEW ARNOLD—T. ARNOLD—W. T. ARNOLD—A. C. BRADLEY—J. COMYNS CARR—J. C. COLLINS—W. J. COURTHOPE—AUSTIN DOBSON—Prof. DOWDEN—E. W. GOSSE—Prof. HALES—W. E. HENLEY—A. LANG—W. MINTO—F. W. H. MYERS—Prof. NICHOL—W. H. PATER—MARK PATTISON—E. J. PAYNE—M. F. ROBINSON—G. SAINTSBURY—Dr. SERVICE—G. A. SIMCOX—Prof. SKEAT—GOLDWIN SMITH—A. SWINBURNE—J. A. SYMONDS—T. H. WARD (the Editor)—Mrs. T. H. WARD—Prof. A. W. WARD—THEODORE WATTS.

"Mr. Ward is to be congratulated, on the whole, in having published an excellently well-selected collection that is not only a pleasant resource for leisure hours, but a methodical hand-book to a poetical education."—*The Times.*

"The work is, moreover, thoroughly well-planned and proportioned. . . . Want of space alone prevents our calling attention in detail to the service which these volumes render to students of our literature."—*Daily News.*

In the press, with 350 Illustrations, Volume I. of

HUMAN MORPHOLOGY:

A TREATISE ON

PRACTICAL AND APPLIED ANATOMY.

By HENRY ALBERT REEVES, F.R.C.S.E.,

Late Lecturer on Anatomy at the London School of Medicine for Women, and formerly Demonstrator of Anatomy at the London and Middlesex Hospitals, Assistant-Surgeon and Teacher of Practical Surgery at the London Hospital, &c.

CONTENTS.

1. Historical Sketch. 2. Introductory Observations. 3. Anatomical Technics. 4. Dissection of the Arm. 5. Dissection of the Leg. 6. Dissection of the Perineum: Glossarial Index.

LONDON: SMITH, ELDER, AND CO., 15, WATERLOO PLACE.

In the Press, with 281 Illustrations, Volume I. of

MANUAL OF PATHOLOGICAL HISTOLOGY.

By CORNIL and RANVIER.

Second Edition, Re-edited and Enlarged. Translated with the approval of the Authors.

Contents:—General Pathological Histology; Lessons of the Tissues.

LONDON: SMITH, ELDER, AND CO., 15, WATERLOO PLACE.

SCIENTIFIC WORTHIES.

The following is a list of the Portraits that have appeared in the above Series.

MICHAEL FARADAY.
THOMAS HENRY HUXLEY.
CHARLES DARWIN.
JOHN TYNDALL.
GEORGE GABRIEL STOKES.
SIR CHARLES LYELL.
SIR CHARLES WHEATSTONE.
SIR WYVILLE THOMSON.
ROBERT WILHELM BUNSEN.
SIR WILLIAM THOMSON.
HERMANN L. F. HELMHOLTZ.
SIR JOSEPH DALTON HOOKER.
WILLIAM HARVEY.
SIR GEORGE B. AIRY.
J. LOUIS R. AGASSIZ.
JEAN BAPTISTE ANDRÉ DUMAS.
RICHARD OWEN.
JAMES CLERK MAXWELL.

Proof impressions of these, printed on India paper, may be had from the Publishers, price 5s. each, or the Set of 18 Portraits in a Handsome Portfolio for £4 15s. carriage paid.

THE PORTFOLIO MAY BE HAD SEPARATELY, PRICE 6s.

Cheques and P.O.O.s payable to MACMILLAN & CO.,

OFFICE OF "NATURE," 29, BEDFORD STREET, STRAND.

Now Ready, price 6s., Vol. XVI., Part I., October, 1881.

THE JOURNAL OF ANATOMY AND PHYSIOLOGY,

NORMAL AND PATHOLOGICAL.

CONDUCTED BY

Professors HUMPHRY, TURNER, and M'KENDRICK.

Contents.

1. Relation of Nerve-Supply to Muscle-Homology. By D. J. Cunningham, M.D.
2. Action of Duboisia on the Circulation. By G. A. Gibson, M.D.
3. Cerebral Sinuses and their Variations. By J. F. Knott, F.R.C.S.I.
4. Primary Growth from Bone, resembling in some Features Scirrhous Carcinoma of Breast. By G. Barling, M.B. (With Figures.)
5. Reproduction of "Feeler" of Lobster's Antenna. By G. B. Howes. (With Figure.)
6. Comparative Anatomy of Lymphatics of Uterus. By G. Hoggan, M.B., and F. E. Hoggan, M.D. (Plates I. and II.)
7. Case of Transposition of Aorta and Pulmonary Artery. By H. Ashby, M.D.
8. Some Points in Histology of Newt. By W. Stirling, M.D.
9. Nerves of Lungs of Newt. By W. Stirling, M.D. (Plates III. and IV.)
10. Pelvimetry. By J. G. Garson, M.D. (Plate V.)
11. Cranial Characters of Admiralty Islanders. By Prof. Turner, M.B.
12. Report on Physiology. By W. Stirling, M.D.
13. Anatomical Notices.

MACMILLAN & CO., London and Cambridge.

WANTED, Clean Copies of NATURE, No. 472, for November 14, 1878. Address—Office of NATURE, 29, Bedford Street, Strand.

ELEMENTS OF NATURAL PHILOSOPHY.

By Professors Sir W. THOMSON, and P. G. TAIT. Part I. Demy 8vo. cloth. *Second Edition*.

THE ELECTRICAL RESEARCHES OF THE

HONOURABLE HENRY CAVENDISH, F.R.S. Written between 1771 and 1781, Edited from the Original Manuscripts in the Possession of the Duke of Devonshire, K.G., by J. CLERK MAXWELL, F.R.S. Demy 8vo, cloth. 18*s*.

"This work, which derives a melancholy interest from the lamented death of the editor following so closely upon its publication, is a valuable addition to the history of electrical research. . . . The papers themselves are most carefully reproduced, and fac-similes of the author's sketches of experimental apparatus. . . . Every department of editorial duty appears to have been most conscientiously performed; and it must have been no small satisfaction to Prof. Maxwell to see this goodly volume completed before his life's work was done."—*Athenæum*.

THE ANALYTICAL THEORY OF HEAT. By

JOSEPH FOURIER. Translated, with Notes, by A. FREEMAN, M.A., Fellow of St. John's College, Cambridge. Demy 8vo. 16*s*.

LECTURES ON TEACHING. Delivered in the Uni

versity of Cambridge in the Lent Term, 1880. By J. G. FITCH, Her Majesty's Inspector of Schools. Crown 8vo, cloth. 6*s*.

"The lectures will be found most interesting, and deserve to be carefully studied, not only by persons directly concerned with instruction, but by parents who wish to be able to exercise an intelligent judgment in the choice of schools and teachers for their children. For ourselves, we could almost wish to be of school age again, to learn history and geography from some one who could teach them after the pattern set by Mr. Fitch to his audience. . . . Mr. Fitch is no less instructive on the art of examination and marking; but this we pass over as leading too far away, and go on to call attention to what he says of the teaching of science. This is so good that we prefer not to make extracts or attempt a summary, but simply advise the reading of the lecture as a whole."—*Saturday Review*.

LOCKE ON EDUCATION. With Introduction and

Notes by the Rev. R. H. QUICK, M.A. Extra fcap. 8vo, cloth. Price 3*s*. 6*d*.
